If the Non-Fatal Error Reporting Enable bit listed in no. 4 is not set, the source due to (1) and (2) stated above will be generated and INT\_SERR\_NONFATAL will not be generated even if writing to the Root Error Status Register has proceeded.

### 35.7.6.5 DMA Interrupt

The DMAC has interrupt functions. It supports two types of interrupt source: one set is for normal operation and the other is for errors. Use the DMAC Interrupt Enable Register to select the interrupt sources and control masking. DMA interrupt notification includes notification by DMA\_INT in the direction of the AXI bus (local bus direction) and notification by issuing an MSI to an other-party RC.

On completion of DMA transfer, either conveying a DMA\_INT interrupt or transmitting an MSI to the RC, but not both, is selected per-channel by a register setting (transmitting an MSI is prohibited in RC mode).

The DMA\_CH\*\_MSI\_EN bits of the DMA Interrupt Vector 0 Register and the DMA Interrupt Vector 1 Register are used to switch the setting (“\*” corresponds to the channel number of a given DMA and per-channel control is possible). If an MSI is to be issued, the value of its traffic class (TC) bits is fixed to 0. The vector value can be specified by using the DMA\_CH\*\_vec bits of these registers.

#### CAUTION

Take care that the specified vector value does not impose a related restriction on the Multiple Message Enable register. For example, if the number set for Multiple Message Enable is 4, the two lower-order bits within the value set for the Message Data are overwritten by the value specified for the DMA\_CH\*\_vec bits, and at that time, specify the value 0b for the higher-order bits that are not overwritten by DMA\_CH\*\_vec bits.

### 35.7.7 Power Management (Root Complex Mode)

#### 35.7.7.1 PCI Power Management (PCI-PM)

An endpoint is placed in non-D0 (the D3 hot state) by changing the setting of the Power State field register of the endpoint by the root complex., which causes a transition of the link state of both RC and EP to L1.

This unit does not support the AUX power supply function. D3 cold is not supported. Implementing the L2 function goes to implementation of L2/L3 ready.

#### (1) Flow of Transition to the L2/L3 Ready State (RC)

##### < For transition via PCIPM L1 >

1. A root complex (RC) issues a config write to change the D-state of an endpoint (EP) to D3 (D3 hot).
2. The RC is automatically placed in L1 by automatic response of the other-party EC.
3. The RC transmits a PME\_Turn\_Off message.
4. Confirm the reception of a PME\_TO\_Ack Message from the EP by reading the value of the PME\_TO\_Ack Receive Interrupt bit (bit 16) in the Message Receive Interrupt Status Register of the RC.
5. Set UI\_ENTER\_L2 of PCIe Core Control 1 Registers to 1b.
6. Confirm the transition to the L2/L3 ready state by reading the value of the LTSSM\_STATE bits (bits [14:8]) in the PCIe Core Status 1 Register (5 higher-order bits [14:10] = 0111xb: L2).

##### < For direct transition to the L2/L3 ready state >

Steps 3 to 6 above apply.

#### (2) Flow of Return from the L2/L3 Ready State (RC)

##### < Return from the L2/L3 ready state by the RC >

1. Assert the following reset signals.  
RST\_B, RST\_GP\_B, RST\_PS\_B, RST\_CFG\_B
2. Deassert the reset signals at a desired time and wait for return to L0 (wait for linkup).
3. If the link is not up, repeat steps 1 and 2.

##### < Return from the L2/L3 ready state by the EP >

1. Wait for the reception of a beacon by the EP. Read the LINKDN bit (0204h, bit 9) in the PCIe Event Interrupt Status register regularly to check whether ELECTRICAL\_IDLE\_BROKEN has been generated.
2. Assert the following reset signals.  
RST\_B, RST\_GP\_B, RST\_PS\_B, RST\_CFG\_B
3. Deassert the reset signals at a desired time, clear UI\_ENTER\_L2 of PCIe Core Control 1 Registers to 0b, and wait for it to return to L0 (wait for linkup).
4. If the link is not up, repeat steps 2 and 3.

### 35.7.7.2 Active State Power Management (ASPM)

The ASPM L0s and L1 states can be used by the setting of the Active State PM Control bits (bits [1:0]) in the Link Control/Status Register (PCIe Configuration Register: 6070h).

**ASPM L0s:** The module is automatically placed in the ASPM L0s state following setting of the Active State PM Control bits to 01b or 11b. When to initiate a transition to this state is determined by judgment of the idle state by the PCIe core.

**ASPM L1:** An RC is placed in the ASPM L1 state in response a request for transition to the ASPM L1 state from an EP following setting of the Active State PM Control bit to 11b. When to initiate a transition to this state is determined by judgment of the idle state by the PCIe core.

A transition to the ASPM L1 state is enabled by setting the UI\_RC\_REJECT\_ASPM\_L1 bit (bit [19]) of the PCIe Core Control 1 Register (offset: 404h) to 0b. To reject a transition to the ASPM L1 state on the RC side, set the UI\_RC\_REJECT\_ASPM\_L1 bit to 1b.

#### Return to the L0 state from the L1 state:

Resuming access from the AXI master side:

Return to the L0 state is initiated in response to the other-party PCIe device resuming access.

Resuming access from the AXI slave side:

The AXI can be returned to the L0 state in response to the AXI starting access to a PCIe device. Access to an AXI configuration register also returns the AXI to the L0 state.

### 35.7.8 Power Management (Endpoint Mode)

#### 35.7.8.1 PCI Power Management (PCI-PM)

The endpoint unit can be placed in the D3 hot state by changing the setting of the Power State field register by the root complex. A PME\_Turn\_Off message can be received even after the transition to the D3 state. The turning-off procedure described below starts in such cases.

**D0:** This is a full-power state in which no restrictions apply. The link state is basically L0. However, if the ASPM generates a source for a transition, the latter takes priority.

**D3hot:** The link state basically changes to L1. By changing the value of the Power State bits of the PM Status/Control register in response to the reception of CfgWr, the unit sets D3\_EVENT to 1 when a transition to the non-D0 state is requested per function, and issues Deassert\_INTx in response to the assertion of any of the INTx signals. The EP should set D3\_EVENT\_ACK to 1 after preparation for low power consumption. After D3\_EVENT\_ACK is set to 1, issuing of the AXI transaction to the PCIe is prohibited.(this does not apply to access to internal registers which include the configuration register).

This unit does not support the AUX power supply function. D3 cold is not supported. Implementing the L2 function goes to implementation of L2/L3 ready.

#### (1) Flow of Transition to the L2/L3 Ready State (EP)

##### < For transition via PCIPM L1 >

1. The D-state of an endpoint (EP) is changed to D3 (D3 hot) in response to the reception of a config write from a root complex (RC).
2. Check that D3\_EVENT has been set to 1, and clear D3\_EVENT\_ACK to 0 after setting it to 1.
3. A transition to the L1 state is automatically initiated.
4. The EC receives a PME\_Turn\_Off message from the RC.
5. Check that TURN\_OFF\_EVENT has been set to 1, and clear TURN\_OFF\_EVENT\_ACK to 0 after setting it to 1.
6. A transition to the L2/L3 ready state is automatically initiated.

##### < For direct transition to the L2/L3 ready state >

Steps 4 to 6 above apply.

## (2) Flow of Return from the L2/L3 Ready State (EP)

### < Return from to the L2/L3 ready state by the RC >

1. Wait for an Electrical Idle exit from the RC.
2. After that, follow the instruction by the RC to return to L0 (the following is an example).
  - Example 2-1. Follow the instruction by the RC to reset the EP (assert RST\_B, RST\_GP\_B, RST\_PS\_B, and RST\_CFG\_B).
  - Example 2-2. Follow the instruction by the RC to release the EP from the reset state at a desired time.
  - Example 2-3. Return to L0.

### < Return from to the L2/L3 ready state by the EP >

1. Check that the value of the LTSSM\_STATE bits (bits [14:8]) in the PCIe Core Status 1 Register is 3Ah.

*Note:* As a criterion for judgment at this time, checking the value read from this register requires consecutively checking the above value several times. Since the value of the LTSSM bits is checked by direct reference to the internal circuit state information, an undefined state value may be read depending on the timing of the operation for transition. To make sure that the current state is the L2 idle state, we recommend checking the state by access more than once. Only check all seven bits of LTSSM\_STATE (bits [14:8]) of the PCIe Core Status 1 Register at this time in the flow of return.

2. Assert the Power Management Event setting input pin to 1b.
3. Assert RST\_B (the EP transmits a beacon).
4. After that, follow the instruction by the RC to return to L0 (the following is an example).
  - Example 4-1. The RC detects the reception of a beacon from the EP and initiates return to L0 on the RC side.
  - Example 4-2. Follow the instruction by the RC to reset the EP (assert RST\_B, RST\_GP\_B, and RST\_PS\_B, RST\_CFG\_B).
  - Example 4-3. Follow the instruction by the RC to release the EP from the reset state at a desired time.
  - Example 4-4. Return to L0.

### 35.7.8.2 Active State Power Management (ASPM)

The ASPM L0 and L1 states can be used by setting the Active State PM Control bits (bits [1:0]) of the Link Control/Status Register (PCIe Configuration Register: 6070h).

Permit a transition to ASPM L1 by setting ALLOW\_ENTER\_L1 to 1.

The ASPM L1 Idle Time bits of the registers must be set in advance to suit the AXI bus specifications (the range of settings is for from 256 to 65536 cycles of ACLK). If transfer does not proceed for the time set in the ASPM L1 Idle Time bits within the unit, the module is automatically placed in the ASPM L1 state.

**ASPM L0s:** A transition to the ASPM L0s state is automatically initiated by setting the Active State PM Control bits to 01b or 11b. When to initiate a transition to this state is determined by judgment of the idle state by the PCIe core, so your operation will not be especially required.

A transition to L0s can be controlled by setting the UI\_ENTER\_TXL0S bit (bit [16]) of the PCIe Core Control 1 Register.

**ASPM L1:** A transition to the ASPM L1 state can be initiated by setting the Active State PM Control bits to 10b or 11b. When to initiate a transition to this state is determined by judgment of the idle state by the PCIe core.

A transition to the L1 state is enabled by setting ALLOW\_ENTER\_L1 to 1.

#### Return from the L1 state to the L0 state

Resuming access from the AXI master side:

Return to the L0 state is initiated in response to the other-party PCIe device resuming access.

Resuming access from the AXI slave side:

The AXI can be returned to the L0 state in response to the AXI starting access to a PCIe device. Access to an AXI configuration register also returns the AXI to the L0 state.

#### (1) ASPM L1 Idle Time Setting

The Mode Set 3 registers (offset: 380h) are defined as the ASPM L1 Idle Time registers. These registers are used to set the counter for monitoring the state of the AXI bus or internal transactions in terms of remaining activity when this unit is placed in the ASPM L1 state. The counter monitors whether the AXI bus and transactions within this unit are idle based on one of the following settings and uses this as the condition for triggering the transition to the ASPM L1 state.

“ASPM L1 Idle Time[7:0]” = 00h: 256 cycles of ACLK

“ASPM L1 Idle Time[7:0]” = 01h: 512 cycles of ACLK

:

“ASPM L1 Idle Time[7:0]” = FFh: 65536 cycles of ACLK

### 35.7.9 Error Processing

Two error reporting paradigms are defined for PCI Express: baseline error reporting capability, which is the minimal requirement, and advanced error reporting (AER) capability, which can provide greater stability, as an optional error reporting facility. Our unit supports both error reporting functions.

#### 35.7.9.1 Error Classification

PCI Express errors are of two types, correctable and uncorrectable. Uncorrectable errors are further classified into two types, non-fatal and fatal.

| Error Type                      | Description                                                                                                                     |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| Correctable Error               | An error which cannot be recovered by hardware                                                                                  |
| Uncorrectable Error (Non-Fatal) | An error which causes a particular transaction in PCI Express to be unreliable (but the PCI Express link itself is functional). |
| Uncorrectable Error (Fatal)     | An error which causes the PCI Express link itself to be unreliable                                                              |

In operation as a root complex, the above types of error are indicated by the individual interrupt names.

- INT\_SERR\_COR
- INT\_SERR\_NONFATAL
- INT\_SERR\_FATAL

### 35.7.9.2 Error Checking Mechanism

#### (1) Physical Layer Error List

The following type of error is to be detected in the physical layer.

- Receiver Error

#### (2) Data Link Layer Error List

The following type of error is to be detected in the link layer.

- Bad TLP Error
- Bad DLLP Error
- REPLAY\_NUM Rollover
- Replay Timer Timeout
- Receiver Overflow Error

#### (3) Transaction Layer Error List

The following type of error is to be detected in the transaction layer.

- Completion Timeout
- Completer Abort
- Unsupported Request
- Unexpected Completion
- Malformed TLP
- Poisoned TLP

### CAUTION

The specifications of the receiver error detection function in each LTSSM state are as listed below.

| LTSSM State   | Unit Specification | Base Spec Specifications |
|---------------|--------------------|--------------------------|
| Configuration | Support            | Gen1/Gen2 (Must)         |
| Recovery      | Non-Support        | Option                   |
| L0            | Support            | Must                     |
| Disabled      | Support            | Option                   |
| Hot Reset     | Support            | Option                   |

### 35.7.9.3 Error Message

The PCI Express Base Specification defines error messages as one of the mechanisms for notifying the system or another device of an error when it is detected by a PCI Express agent.

| Error Message | Description                                            |
|---------------|--------------------------------------------------------|
| ERR_COR       | Used when a correctable error is detected              |
| ERR_NONFATAL  | Used when a non-fatal, uncorrectable error is detected |
| ERR_FATAL     | Used when a fatal, uncorrectable error is detected     |

#### Advisory Non-Fatal Error

The PCI Express Base Specification states that when a PCI Express agent as the detecting agent detects a non-fatal error, it handles the error as an advisory non-fatal error whether it does or does not support AER. In handling a non-fatal error as an advisory non-fatal error, the agent sends an ERR\_COR message instead of an ERR\_NONFATAL message and sends an advisory notification to the software. At this time, the advisory non-fatal error status bit of the correctable error status register is set to indicate the error state. Note that subsequent setting of the first error pointer register, logging of the header, and message transmission only proceed if the Advisory Non-Fatal Error Mask bit of the Correctable Error Mask Register is clear (no masking). They do not proceed if the bit is set.

The error cases which are handled as advisory non-fatal errors are as follows.

- Reception of unsupported non-posted requests
- Reception of a non-posted request with a completer abort completion response
- Reception of an unexpected completion
- Reception of a poisoned TLP (this is not handled as an advisory non-fatal error in this core)
- Detection of a completion timeout (this is not handled as an advisory non-fatal error in this core)

This unit may merge multiple error messages with the same ID. This would occur when multiple errors are detected during the wait for the unit to be ready for the transmission of messages after an error condition is detected. However, messages will not always be merged in such cases.

## 35.8 Operation

### 35.8.1 Setting Up

Set the internal registers of the unit including the configuration registers.

This section explains the procedure for setting up until the PCI Express link is up (the module is ready for data transfer).

Figure 35.8-1 Setting Up

### 35.8.1.1 Changing the Initial Values of the Registers

Of the internal registers, the initial values of the configuration registers can be changed via the AXI slave interface.

#### 1) AXI Bridge Registers

De-asserting ARESETn following supply of CLK allows access to these registers. In the case of resetting of the PCIe core, write to the registers while the reset signal is being asserted.

#### 2) PCIe Configuration Register

De-asserting ARESETn following supply of CLK allows access to these registers. Of the reset signals of the PCIe core, those related to the configuration register must be de-asserted.

### (1) Setting the Initial Values of the Registers

The initial values of the registers listed below are 0. Set appropriate values in the registers before the start of link up.

- Device ID
- Vendor ID
- Class Code (base class/sub-class/programming interface)
- Revision ID
- Subsystem ID
- Subsystem Vendor ID

### 35.8.1.2 De-asserting the Reset

In this unit, software reset control by the register is possible.

De-asserting of the reset of the core (the reset register in the case of register control) automatically starts operations such as receiver detection and the training sequence with the other-party device.

Note that our unit requires a wait of at least 5 ms from power-on to de-assertion of the reset.

Check that link negotiation with the other party has been completed and the link with the unit is up.

### 35.8.1.3 Checking if the Link is Up

Checking if the link is up can be done through either of the following methods. This is usually done by the root complex.

#### 1) Polling

Have the CPU of the chip poll the DL\_Down Status bit (bit [0]) of the PCIe core Status 1 Register in AXI bridge registers until the value of the bit is 0 (indicating the DL\_Up state).

#### 2) Interrupt

After assertion of the PCIE\_EVT\_INT pin of the interrupt signal, check the interrupt source by reading the DL\_UpDown bit (bit [9]) in the PCIe Event Interrupt Status 0 register in AXI Bridge Registers. After that, check that the DL\_Down Status bit (bit [0]) of the PCIe Core Status 1 Register is 0 (indicating the DL\_Up state)

The settings above make the unit ready for transfer with the other party device.

However, data transfer such as reading or writing memory is not yet possible in this state. This requires subsequent window settings.

### 35.8.2 Setting the Windows (Root Complex Mode)

When using the window settings in the root complex configuration, the recommended settings in the BAR and BAR Mask registers are “BAR: All 0s” and “BAR Mask: All 1s”.

### 35.8.3 Setting the Windows (Endpoint Mode)

All PCI Express commands are issued via the set memory spaces or register spaces. After making the window settings and the configuration register settings, data such as PCIe MRd and MWr can be transferred. All PCI Express commands are issued via the set memory spaces or register spaces. After making the window settings and the configuration register settings, data can be transferred in response to PCIe MRd and MWr requests and so on.

### 35.8.3.1 BAR Specification (Two-Function Configuration)

Our unit has functionality for dividing the 64-bit memory space into window spaces for AXI access. Windows for access from PCIe to AXI and from AXI to PCIe are respectively referred to as AXI windows and PCI windows.

The AXI Bridge Registers (unit-specific registers) are accessible regardless of the function being used.

The 64-bit memory spaces must be set exclusively of each other and have no overlaps.

Set the AXI window spaces such that they do not overlap.

Table 35.8-1 Example BAR Settings (64 bits × 3, Function = 2)

| Function    | BAR (Memory Space)                      | AXI Window | Note                 |
|-------------|-----------------------------------------|------------|----------------------|
| Function #0 | 64-bit memory space (1)<br>{BAR1, BAR0} | AXI #0     |                      |
|             |                                         | AXI #1     |                      |
|             |                                         | AXI #2     |                      |
|             |                                         | AXI #3     |                      |
|             | 64-bit memory space (2)<br>{BAR3, BAR2} | AXI #4     |                      |
|             |                                         | AXI #5     |                      |
|             |                                         | AXI #6     |                      |
|             |                                         | AXI #7     |                      |
|             | 64-bit memory space (3)<br>{BAR5, BAR4} | —          | AXI Bridge Registers |
|             |                                         |            |                      |
|             |                                         |            |                      |
|             |                                         |            |                      |
| Function #1 | 64-bit memory space (1)<br>{BAR1, BAR0} | AXI #0     |                      |
|             |                                         | AXI #1     |                      |
|             |                                         | AXI #2     |                      |
|             |                                         | AXI #3     |                      |
|             |                                         | AXI #4     |                      |
|             |                                         | AXI #5     |                      |
|             |                                         | AXI #6     |                      |
|             |                                         | AXI #7     |                      |
|             | 64-bit memory space (2)<br>{BAR3, BAR2} | —          | Not allocated        |
|             |                                         |            |                      |
|             | 64-bit memory space (3)<br>{BAR5, BAR4} | —          | AXI Bridge Registers |
|             |                                         |            |                      |

**Remarks** BAR: Abbreviation of Base Address Register

**Note:** The address spaces are invalid when the corresponding BAR values are all 0s.  
The BAR settings are required for each function.

The base addresses of the 64-bit memory spaces (1), (2), and (3) above are set by using the following configuration registers.

- 64-bit memory space (1): Configuration registers {BAR1, BAR0}
- 64-bit memory space (2): Configuration registers {BAR3, BAR2}
- 64-bit memory space (3): Configuration registers {BAR5, BAR4}

**CAUTION**

---

- Up to eight AXI windows can be set by dividing the 64-bit memory space (1).
  - Up to eight AXI windows can be set by dividing the 64-bit memory space (2).
  - The number of AXI windows allocated to each of the BAR areas is as follows.  
64-bit memory space (1): 64-bit memory space (2) = 8:0 or 4:4;  
Select either of the above settings. Note that all of the allocated AXI windows do not need to be used effectively.
  - The 64-bit memory space (3) is dedicated for access to the AXI Bridge Registers.
  - The base addresses of each of the AXI windows are limited within the 4-Gbyte space from the BAR base address.
-

### 35.8.3.2 Setting the AXI Windows

In operation as an endpoint device, the AXI windows can be set in the following two ways.

1. The root complex issuing memory read and memory write requests.
2. Setting from the CPU of the endpoint under software control.

The following shows the procedure for making the settings by method 1.

Set the AXI windows on the endpoint side by issuing memory read (MRd) and memory write (MWr) requests to the AXI Bridge Register access space set in the previous section.

Data transfer is possible when setting of the windows is completed and the Bus Master Enable bit and the Memory Space Enable bit of the given configuration register are set to the enabled state.

The following shows the procedure for making the settings by method 2.  
The AXI windows can be set by write access to the registers through the AXI slave interface.

Figure 35.8-2 Example Settings of the AXI Windows

At this time, three address space settings, namely the AXI address space for the root complex device, the AXI address space for the endpoint device, and the PCI address space between the root complex and the endpoint, must be consistent within the system. If they are not, data cannot be transferred. Take care with the settings.

### 35.8.3.3 Setting the PCIe Address Space

A PC or similar system recognizes information on the areas of the memory space which are required by other-party endpoint devices by access to the configuration registers of the endpoints through software processing by the CPU on the root-complex side. In the case of embedded systems, etc., the areas required by the other-party devices will generally be known in advance, so this processing is not usually required.

The following is an example procedure for setting of the PCIe memory space for an other-party endpoint by the root complex.

Configuration requests are made to be issued to the other-party endpoint devices by register access through the AXI slave interface.

Figure 35.8-3 Example Settings for the PCIe Address Space

After issuing a configuration write request for writing all 1s (FFFF\_FFFFh), a configuration read request is issued and if the result of reading is all 0s (0000\_0000h), the given base address register (BAR) is judged to be reserved and the corresponding space is considered to be unused.

From the result of reading, software on the root complex side writes the base address (the lower-limit address) of the PCI address space to be allocated to the endpoint device by issuing a configuration write request.\*<sup>1</sup> At this time, setting of a BAR for which the area requested by the endpoint device was found to be reserved and thus unused is not required.

Also, if an address space which includes the other party has been prepared in advance, the above confirmation is not required. Set the base address directly.

**Note 1.** Setting a base address register to all 0s is prohibited.

The completion of settings for the PCIe address space means that the root complex is ready for data transfer to the corresponding endpoint. Finally, set the Bus Master Enable bit and the Memory Space Enable bit of the given command register to enable the memory space.

### 35.8.4 Data Transfer

This unit has one port each for master and slave operation as an AXI interface. For PCIe requests which can be issued through the master and slave ports, see **Section 35.7.2, Issuing of PCIe Requests and Register Access (by AXI)** and **Section 35.7.3, Initiation of AXI Transactions and Register Access (by PCIe)**.

The focus of this explanation is on normal memory data transfer.

#### 35.8.4.1 PCIe MWr (when the AXI Slave is in Use)

A write transaction from the AXI bus (AXI-WR) via a window set as a PCIe window is converted into an MWr command (PCIe MWr) and then issued. If a PCIe MWr request is to be issued through the AXI interface slave port of the unit by using a DMAC, etc. external to the unit, the number of write transactions which can be accepted at a time is one, so the operation is as follows.

1. A write transaction from the AXI bus is issued through the AXI slave interface (write address channel, write data channel).
2. The transaction is converted into a PCIe MWr command and data are transferred to the other-party device via the PCIe bus.
3. After a wait for a response from the AXI slave interface (write response channel), a next AXI write transaction is issued.

A write response is issued after writing data to the transmission buffer (SRAM) within the unit. If this transmission buffer is full, the unit receives as much data as it can capture and then places the READY signal at the low level. Accordingly, the AXI bus may be placed in the hold state during transfer.

Since this depends not only on the specifications of the PCIe module (the number of lanes, rate, maximum payload size, etc.) but also on the size of the transmission buffer, the size of the reception buffer of the other-party device, and the external system configuration (the time for access to the external DRAM, etc.), care should be taken when considering the system configuration in general.

### 35.8.4.2 PCIe MWr (when the DMAC is in Use)

If a PCIe MWr request is to be issued through the AXI master port by using the DMAC within the unit, the number of requests which can be read by the internal DMAC is one transaction per channel, so the operation is as follows.

1. An AXI read (AXI-RD) request is issued through the AXI master interface (read address channel).
2. After the AXI master interface (read data channel) receives read data, this is converted into a PCIe MWr command and data are transferred to the other-party device via the PCIe bus.
3. Following the completion of the reception of read data, a next AXI-RD is issued.
4. The above steps are repeated until transfer of all bytes set in the DMA Size bits is completed.

The read data channel checks that the data that have been read are valid and indicates the readiness of the data for reception. Even when the transmission buffer (SRAM) within the unit is full, the unit issues read requests through the read address channel. Also, it receives as much data as it can capture and places subsequent data in the non-receivable state. Accordingly, depending on the state of the transmission buffer, data may not be transferred regardless of a request having been issued, or the AXI bus may be placed in the hold state during transfer. This lengthens the period of waiting for data that have been read, leading to the deterioration of transfer performance as well as the deterioration of overall system performance.

Likewise, contention with write access by the slave interface and contention in write access between channels may decrease performance in transfer.

Since this depends not only on the specifications of the PCIe module (the number of lanes, rate, maximum payload size, etc.) but also on the size of the transmission buffer, the size of the reception buffer of the other-party device, and the

external system configuration (the time for access to the external DRAM, etc.), care should be taken when considering the system configuration in general.

The following is an example where the number of requests which can be read by the AXI master interfaced through four DMAC channels is 4.

1. An AXI read (AXI-RD0; DMAC ch. 0) request is issued through the AXI master interface (read address channel).
2. Since the number of requests which can be read by the unit = 4, AXI read requests are subsequently issued through DMAC ch. 1, ch. 2, and ch. 3.

*Note:* No order of priority applies to the issuing of requests through these channels.

3. Following the completion of the reception of data read in response to the read request through ch. 0, ch. 0 is able to issue a next AXI-RD0.
4. The above steps are repeated until transfer of all bytes set in the DMA Size bits for each channel is completed.

Configuring data transfer as described above allows increased performance, although such a configuration complicates software control.

### 35.8.4.3 PCIe MRd (when the AXI Slave is in Use)

In usage as an AXI slave, memory read requests (PCIe MRd) are issued to the PCIe interface, a completion (CplD) is received from the PCIe interface, and an AXI write transfer (AXI-WR) is initiated (this unit supports eight outstanding transfers). Therefore, only the number of PCIe MRd requests that corresponds to this set number of outstanding transfers can be issued first, regardless of the reception of CplD. The received CplDs are stored in a data buffer (RAM) and then transferred through the AXI bus.

If a PCIe MRd is issued through the AXI interface slave port of the unit, the number of read requests which can be accepted by the AXI slave at a time = 1 to 8 corresponding to the PCIe section.

When Outstanding = 1

When Outstanding = 4

**When outstanding = 1**

1. An AXI read transaction is issued through the AXI slave interface (read address channel).
2. A transaction is converted into a PCIe MRd command and the request for data reading is issued to the other-party device via the PCIe bus.
3. CplD is received from the other-party device and an AXI read response is issued through the AXI slave interface (read data channel).
4. Steps 1 to 3 are repeated.

**When outstanding = 4**

1. An AXI read transaction is issued through the AXI slave interface (read address channel).
2. A transaction is converted into a PCIe MRd command and the request for data reading is issued to the other-party device via the PCIe bus.  
Steps 1 and 2 can be repeated until up to four consecutive requests have been issued.
3. CplD is received from the other-party device and an AXI read response is issued through the AXI slave interface (read data channel).  
At this time, the PCIe module can operate with out-of-order transactions, so the order of CplDs from the other-party device may not be preserved. The unit also includes a buffer to support in-order transactions with the AXI bus. If this is used and the CplD for a preceding PCIe MRd is never returned, however, the next request cannot be issued and performance deteriorates accordingly.  
After that, steps 1 to 3 are repeated.

### 35.8.4.4 PCIe MRd (when the DMAC is in Use)

If a PCIe MRd request is to be issued by using the DMAC within the unit, the overall number of requests is also 1 to 8 when the DMAC is incorporated depending on the number of outstanding transfers.

1. Activate the internal DMAC through the AXI slave interface or from an other-party device.

**When outstanding = 1**

2. The DMAC issues a read request and this is converted to a PCIe MRd command within the unit. The request for data reading is issued to the other-party device via the PCIe bus.
3. CplD is received from the other-party device and an AXI write transaction is issued through the AXI master interface (write address channel, write data channel).
4. Following the completion of the AXI write transfer, a next request is issued.
5. Steps 2 to 4 are repeated until transfer of all bytes set in the DMA Size bits is complete

**When outstanding = 4**

2. The DMAC issues a read request and this is converted to a PCIe MRd command within the unit. The request for data reading is issued to the other-party device via the PCIe bus. Up to four consecutive requests can be issued.
3. CplD is received from the other-party device and an AXI write transaction is issued through the AXI master interface (write address channel, write data channel).  
At this time, the PCIe module can operate with out-of-order transactions, so the order of CplDs from the other-party device may not be preserved. The unit also includes a buffer to support in-order transactions with the AXI bus. If this is used and the CplD for a preceding PCIe MRd is never returned, however, the next request cannot be issued and performance deteriorates accordingly.
4. Following the completion of the AXI write transfer, a next request is issued.
5. Steps 2 to 4 are repeated until transfer of all bytes set in the DMA Size bits is completed.

## 35.9 Points for Caution and Restrictions

### 35.9.1 Points for Caution and Prohibited Items in the Issuing of Requests

The following describes the restrictions in the issuing of various requests.

#### (1) Prohibition of fixed bursts of 2 or more beats

Fixed bursts for 2 or more beats are prohibited. If an attempt to use these is made, an OKAY response is returned to the AXI bus, but this may lead to issuing of the unexpected requests to the PCIe side, or unexpected register access which will change register values, and so on.

#### (2) Points for caution in the issuing of special requests

The requests listed below are issued by access to the internal registers. The registers are only accessible from the AXI side and writing to them while requests are being processed is prohibited. Attempted access from the PCIe side will be ignored.

[Special Requests]

- Zero-Length Memory Read Request
- Configuration Read
- Configuration Write
- Message Request
- Message Request with data payload

**CAUTION:** Do not issue a special request for which issuing of the request is prohibited. Operation is not guaranteed if this is done.

### 35.9.2 Ordering Specifications of Received Non-Posted and Posted Requests

In the specifications of this unit, a non-posted request is not overtaken by a posted request on the receiving side.

Requests received from another party are output to the higher-level bus in the order of reception.

### 35.9.3 Caution when Changing the Speed Spontaneously by the EP Unit

Follow the procedure below. The following control bits are present in the PCI Core Control 2 Register and PCI Core Status 2 Register among the AXI-Bridge registers.

1. Wait until the home node is placed in the L0 state.
2. Read the value of the STATE\_DATA\_RATE\_IDENTIFIER\_RECEIVED bit to check the supported speed of the other-party node.
3. If the home node supports the speed to which the other-party node wants to change, set the UI\_LINK\_SPEED\_CHANGE[1:0] bits and assert the UI\_LINK\_SPEED\_CHANGE\_REQ bit.
4. Wait for the UI\_LINK\_SPEED\_CHANGE\_DONE bit to be asserted (wait for the completion).

**CAUTION:** UI\_LINK\_SPEED\_CHANGE\_REQ is retained until UI\_LINK\_SPEED\_CHANGE\_DONE is asserted. It should be de-asserted after checking the assertion of UI\_LINK\_SPEED\_CHANGE\_DONE.

### 35.9.4 Error Processing of Unsupported Requests

The following describes the flow of processing for error reporting and error logging.

(1) Access that straddles a 4-KB boundary

Data transfer to a memory space which straddles a 4-KB boundary cannot proceed (this is stipulated by the PCI Express Base Specification). In our unit, the reception of a memory write or read request for a memory space which straddles a 4-KB boundary is handled as a malformed TLP.

(2) RCB violations

The PCI Express Base Specification states that error processing in response to violations of the read completion boundary (RCB) is optional. The PCIe module of this LSI chip does not support the detection of RCB violations at the time of the reception of completion responses. Support for this function should be handled by the user logic.

(3) Error processing in response to byte enable fields

The PCI Express Base Specification states that error processing in response to Byte Enable fields is optional. Our unit does not support the detection of errors in the form of violations of Byte Enable rules. Support for this function should be handled by the user logic.

(4) Request that extends beyond the base address boundary

This core does not detect a request that starts within the range set in the Base Address Register but extends beyond the boundary from the base address as an error. Such a request should be handled by the user logic

(5) Processing when a TLP that is ready to be transferred by the transmitter is a malformed TLP

Even if malformation of a TLP that is ready to be transferred by the transmitter is detected, due to the detection of parity errors when it is read from the FIFO buffer and so on, this unit does not suspend the transmission of such a TLP. Received malformed TLPs must be handled appropriately by other-party devices.

### 35.9.5 Processing on Reception of the Message

The following lists the messages to be detected as a silent drop or UR on reception of the given message.

Table 35.9-1 Operations on Message Reception

| Received Message      | Root Complex      | Endpoint          |
|-----------------------|-------------------|-------------------|
| Assert_INTx           | Normal processing | Silent Drop       |
| Deassert_INTx         | Normal processing | Silent Drop       |
| ERR_COR               | Normal processing | Silent Drop       |
| ERR_NONFATAL          | Normal processing | Silent Drop       |
| ERR_FATAL             | Normal processing | Silent Drop       |
| UNLOCK                | Silent Drop       | Silent Drop       |
| Set_Slot_Power_Limit  | Silent Drop       | Normal processing |
| Vendor_Defined_Type0  | UR                | UR                |
| Vendor_Defined_Type1  | Silent Drop       | Silent Drop       |
| Ignore                | Silent Drop       | Silent Drop       |
| LTR                   | UR                | UR                |
| OBFF                  | UR                | UR                |
| PM_PME                | Normal processing | Silent Drop       |
| PME_TO_Ack            | Normal processing | Silent Drop       |
| PM_Active_State_Nak   | Silent Drop       | Normal processing |
| PME_Turn_Off          | Silent Drop       | Normal processing |
| PTM_Request           | UR                | UR                |
| PTM_Response          | UR                | UR                |
| PTM_ResponseD         | UR                | UR                |
| Invalidate_Request    | Silent Drop       | UR                |
| Invalidate_Completion | Normal processing | Silent Drop       |
| Page_Request          | UR                | UR                |
| Page_Response         | UR                | UR                |

**Note:** Silent Drop: Normal completion, data are not reflected  
UR: Unsupported Request

### 35.9.6 Other Points for Caution

(1) Access after the de-assertion of the reset signal

When a cycle of writing starts before the value of the SAWREADY bit has become 1b following the de-assertion of the reset signal, access in the second and subsequent cycles produces slave errors.

After the reset signal has been de-asserted, do not assert the SAWVALID signal until SAWREADY has become 1.

(2) Point for caution at times of register writing

In some cases of writing 2DW or more and skipping over with the use of byte enable to a register from the AXI side, writing might not proceed as expected.

Using a pin reset or register reset from the AXI side as a non-consecutive SWSTRB, restricts writing to no more than 1DW (32 bits).

(3) Point for caution on register reading

In the case of reading a register from the AXI side, values read from invalid byte lanes are from undefined outputs (meaningless garbage data).

(4) Generation of unexpected correctable errors

A correctable error may be detected at the time of EIOS reception following low power state transitions of this unit such as from L0s to L1. If this happens, processing to send a message or assert an interrupt flag signal is to proceed. Take care on this point and respond appropriately so that a correctable error is not handled as a fatal error (a mask setting by a register to switch the notification of unexpected correctable errors off is recommended).

(5) Reset interval in transitions from a hot reset to detection in RC mode

In generations of PCI Express after Gen1, at the time of transitions from a hot reset to detection in accord with the operating rate, the base specification prescribes securing a 1-ms waiting interval for changes to the rate, so secure a reset interval of 1 ms.

## Section 36 Ethernet MAC Interface (ETHER)

This section describes the functions of the Ethernet MAC interface (ETHER).

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 36.1 Overview

The EthernetAVB-IF includes an Ethernet controller (MAC) that conforms to the definition of the MAC (Media Access Control) layer for Ethernet in the IEEE 802.3 standard.

When connected with a physical-layer LSI chip (PHY-LSI) that complies with the standard, the MAC is able to transmit and receive Ethernet (IEEE 802.3) frames. The MAC has a single MAC layer interface.

The EthernetAVB-IF has a dedicated direct memory access controller (AVB-DMAC) for transferring transmitted Ethernet frames to and received Ethernet frames from respective storage areas in the User RAM (URAM) at high speed.

The AVB-DMAC is compliant with the following three standards formulated for IEEE 802.1BA: the IEEE 802.1AS timing and synchronization protocol, the IEEE 802.1Qav real-time transfer, and the IEEE 802.1Qat stream reservation protocol.

In this section, URAM refers to the local RAM and external memory for the SoC.

#### 36.1.1 Features

**Table 36.1-1** lists the specifications of the EthernetAVB-IF module.

Table 36.1-1 Specifications (Functions)

| Item                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Protocol                               | Flow control conforming with the IEEE 802.3x standard                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Data transmission and reception        | Transmission and reception of Ethernet (IEEE 802.3) frames                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Section 37 IIC Bus Interface (IIC)

This section describes the functions of the IIC bus interface (IIC).

### 37.1 Functional Overview

This section describes the functions of the IIC bus interface (IIC).

The IIC has a total of four channels from ch. 0 to ch. 3. Of those, ch. 1 and to ch. 3 are for use with the ISP support package, so using registers related to those channels is prohibited.

#### 37.1.1 Features

- This interface uses two lines, the serial clock (SCL) and the serial data bus (SDA), to transfer data to and from multiple devices.
- The data length is 8 bits.  
(However, one bit of the ACK signal is attached after the 8-bit data.)
- This interface conforms to the IIC bus format (THE I2C-BUS SPECIFICATION VERSION 2.1 issued by Philips Semiconductors in January 2000). (However, it does not support the high speed mode: 3400 kbits/s.)
- Supports the standard mode (maximum transfer rate: 100 kbits/s) and the fast mode (maximum transfer rate: 400 kbits/s).
- The input clock consists of a single PCLK.
- The “High” level width and “Low” level width of the serial clock (SCL) can be set.
- The bus line status can be used to determine “start condition” and “stop condition”.
- The double buffers allow data to be sent and received continuously.

37.1.2 Connection Configuration

Figure 37.1-1 shows the connection configuration of the IIC.

Figure 37.1-1 Connection Configuration

## 37.2 Block Diagram

|                | SDAO0    | Output | Serial data output<br>When the operation is stopped, "High" level is output.                                                                                                              |
| Interrupt pin  | IICBTIA  | Output | Data transmission/reception interrupt output<br>The signal is generated when transmitting and receiving addresses and data.<br>The interrupt is a pulse of one clock cycle width in PCLK. |
|                | IICBTIS  | Output | Status interrupt output<br>This signal is generated by arbitration loss, NACK reception, or detection of a stop condition. The interrupt is a pulse of one clock cycle width in PCLK.     |

## 37.4 Register Description

### 37.4.1 Base Addresses of Registers

For the base addresses of the registers (<IIC0\_S0\_base>, <IIC1\_S0\_base>, <IIC2\_S0\_base>, <IIC3\_S0\_base>), see the Address Map section.

### 37.4.2 List of Registers

**Table 37.4-1** is a list of registers.

Table 37.4-1 List of Registers

| Offset Address | Register Name                          | Abbreviation   | Initial Value | Access Unit (bits) |
|----------------|----------------------------------------|----------------|---------------|--------------------|
| 00h            | IICB data register                     | IICm_IICB0DAT  | 0000_0000h    | 32                 |
| 04h            | IICB slave address register            | IICm_IICB0SVA  | 0000_0000h    | 32                 |
| 08h            | IICB control register 0                | IICm_IICB0CTL0 | 0000_0000h    | 32                 |
| 0Ch            | IICB trigger register                  | IICm_IICB0TRG  | 0000_0000h    | 32                 |
| 10h            | IICB status register 0                 | IICm_IICB0STR0 | 0000_0000h    | 32                 |
| 14h            | IICB status register 1                 | IICm_IICB0STR1 | 0000_0000h    | 32                 |
| 18h            | IICB status clear register             | IICm_IICB0STRC | 0000_0000h    | 32                 |
| 20h            | IICB control register 1                | IICm_IICB0CTL1 | 0000_0000h    | 32                 |
| 24h            | IICB low-level width setting register  | IICm_IICB0WL   | 0000_03FFh    | 32                 |
| 28h            | IICB high-level width setting register | IICm_IICB0WH   | 0000_03FFh    | 32                 |
| 2Ch            | IICB emulation read register           | IICm_IICB0EDAT | 0000_0000h    | 32                 |
| 30h            | IICBS shift register                   | IICm_IICB0DATS | 0000_0000h    | 32                 |

**Note:** (m = 0 to 3)

## 37.5 Register Descriptions

The function description of each register is given below.

The prefix (IICm\_) of the register names is omitted in the register descriptions and the field descriptions in this section.

### 37.5.1 IICB Data Register (IICm\_IICB0DAT) (m = 0 to 3)

The IICB0DAT register is used to send and receive transfer data.

This register is also initialized by changing the IICB0CTL0.IICB0IICE bit from 1 to 0 and the IICB0CTL0.IICB0IICE bit from 0 to 1.

*Note 1:* To become a master in single transfer mode or continuous transfer mode, set the IICB0TRG.IICB0STT bit = 1 and then write to the IICB0DAT register only once to transfer the address and communication direction.

*Note 2:* When transferring data in single transfer mode, writing to the IICB0DAT register in the communication state excluding the wait period is prohibited.

*Note 3:* When transferring data in continuous transfer mode, write to the IICB0DAT register only once for each IICBTIA0 interrupt request signal.

*Note 4:* Do not read the IICB0DAT register during transmission. Similarly, do not write to the IICB0DAT register during a receive operation.

**Access Size:** 32 bits

**Address(es):** <IIC0\_S0\_base> + 0000h  
<IIC1\_S0\_base> + 0000h  
<IIC2\_S0\_base> + 0000h  
<IIC3\_S0\_base> + 0000h

**Initial Value:** 0000\_0000h

### 37.5.2 IICB Slave Address Register (IICm\_IICB0SVA) (m = 0 to 3)

The IICB0SVA register stores the IICB0 bus slave address.

*Note:* Writing to IICB0SVA is prohibited when IICB0CTL0.IICB0IICE = 1.

**Access Size:** 32 bits  
**Address(es):** <IIC0\_S0\_base> + 0004h  
 <IIC1\_S0\_base> + 0004h  
 <IIC2\_S0\_base> + 0004h  
 <IIC3\_S0\_base> + 0004h  
**Initial Value:** 0000\_0000h

| 7 to 1       | IICB0SVA[7:1] | Stores the IICB bus slave address.<br>By comparing the received address with the IICB0SVA register, address match or address mismatch is judged.<br>If the received address matches the IICB0SVA register, the IICB0STRn.IICB0SSCO bit is set to 1b. |
| 0            | —             | Reserved. This bit is read as 0b. The write value should always be 0b.                                                                                                                                                                               |

### 37.5.3 IICB Control Register 0 (IICm\_IICB0CTL0) (m = 0 to 3)

The IICB0CTL0 register controls the operation of this unit.

**Access Size:** 32 bits

**Address(es):** <IIC0\_S0\_base> + 0008h  
<IIC1\_S0\_base> + 0008h  
<IIC2\_S0\_base> + 0008h  
<IIC3\_S0\_base> + 0008h

**Initial Value:** 0000\_0000h

### 37.5.4 IICB Trigger Register (IICm\_IICB0TRG) (m=0 to 3)

The IICB0TRG register is used to set the trigger for this unit.

**Access Size:** 32 bits

**Address(es):** <IIC0\_S0\_base> + 000Ch  
<IIC1\_S0\_base> + 000Ch  
<IIC2\_S0\_base> + 000Ch  
<IIC3\_S0\_base> + 000Ch

**Initial Value:** 0000\_0000h

### 37.5.5 IICB Status Register 0 (IICm\_IICB0STR0) (m=0 to 3)

The IICB0STR0 register indicates the status of this unit and the bus.

When the IICB0CTL0.IICB0IICE bit = 0b, write operation is also possible.

This register is also initialized by changing the IICB0CTL0.IICB0IICE bit from 1 to 0 and the IICB0CTL0.IICB0IICE bit from 0 to 1.

**Access Size:** 32 bits

**Address(es):** <IIC0\_S0\_base> + 0010h  
<IIC1\_S0\_base> + 0010h  
<IIC2\_S0\_base> + 0010h  
<IIC3\_S0\_base> + 0010h

**Initial Value:** 0000\_0000h

| 0            | IICB0ALDF | <p>Arbitration loss detection flag</p> <p>0b : Do not detect</p> <p>1b: Loss of arbitration</p> <p>&lt;Set condition&gt;</p> <ul style="list-style-type: none"> <li>When arbitration loss is detected.</li> </ul> <p>&lt;Clearing condition&gt;</p> <ul style="list-style-type: none"> <li>IICB0STRC.IICB0CLAF bit = 1 write.</li> </ul> <p>If the set condition and clear condition are detected at the same time, the set condition has priority.</p> <p>When arbitration loss is detected, the IICB0STR0.IICB0SSMS and IICB0STR0.IICB0SSTR bits are cleared to 0b (SCLm and SDAm are set to the high impedance state and the bus is released).</p> <p><i>Note:</i> If the IICB0STR0.IICB0ALDF bit is set 1b due to arbitration loss, the IICBTIA interrupt request signal or IICBTIS interrupt request signal is generated. When IICB0STR0.IICB0ALDF bit = 1 is confirmed by the interrupt request signal, clear IICB0STR0.IICB0ALDF bit with IICB0STRC.IICB0CLAF bit. If the IICB0STR0.IICB0ALDF bit is not cleared and 1b remains in the IICB0STR0.IICB0ALDF bit, the IICBTIS interrupt request signal is generated when the interrupt timing occurs even during unrelated communication.</p> |

### 37.5.6 IICB Status Register 1 (IICm\_IICB0STR1) (m = 0 to 3)

The IICB0STR1 register indicates the serial bus status.

*Note:* Even in the loop back mode (IICB0CTL1.IICB0MDLB bit = 1b), the external serial clock signal (SCLm) and serial transmission/reception data signal (SDAm) are read.

**Access Size:** 32 bits

**Address(es):** <IIC0\_S0\_base> + 0014h  
<IIC1\_S0\_base> + 0014h  
<IIC2\_S0\_base> + 0014h  
<IIC3\_S0\_base> + 0014h

**Initial Value:** 0000\_0000h

### 37.5.8 IICB Control Register 1 (IICm\_IICB0CTL1) (m = 0 to 3)

The IICB0CTL1 register controls the operation of this unit.

*Note:* Writing to the IICB0CTL1 register when the IICB0CTL0.IICB0IICE bit = 1b is prohibited.

**Access Size:** 32 bits

**Address(es):** <IIC0\_S0\_base> + 0020h

This bit is read as 0b. The write value should always be 0b.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                             |                                                              |                                                         |                  |         |            |                    |         |         |
| 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | IICB0SLSE                                                    | <p>Specifies enabling or disabling of start condition issuance in the initial communication state.</p> <p>0b: Start condition issuance disabled in the initial communication state<br/>1b: Start condition issuance enabled in the initial communication state</p> <p>By setting the IICB0CTL1.IICB0SLSE bit to 1b, a start condition can be issued by setting the IICB0TRG.IICB0STT bit = 1b in the initial communication state (After the IICB0CTL0.IICB0IICE bit = 1b is set until the stop condition is detected).</p> <p>The IICB0CTL1.IICB0SLSE bit is automatically cleared even if 0b is not written when a start condition is detected.</p> <p><i>Note:</i> Set the IICB0CTL1.IICB0SLSE bit to 0b when participating in other communications unpunctually. If the IICB0TRG.IICB0STT bit is set to 1b after setting the IICB0CTL1.IICB0SLSE bit to 1b while other communications is being performed, other communication may be destroyed.</p> |                                             |                                                              |                                                         |                  |         |            |                    |         |         |
| 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | IICB0SLRS                                                    | <p>Specify enabling or disabling of the communication reservation function.</p> <p>0b: Communication reservation function enabled<br/>If the IICB0CTL1.IICB0SLRS bit is 0b (clear) and this unit is not operating as a master and the bus is in use, setting the IICB0TRG.IICB0STT bit to 1b sets the communication reservation status. By checking the IICB0STR0.IICB0SSRS bit, it can be confirmed whether it is in the communication reserved state.</p> <p>1b: Communication reservation function disabled<br/>If this unit is not participating in communication as a master and the IICB0TRG.IICB0STT bit is set to 1b while the bus is in use, the IICB0STR0.IICB0STCF bit = 1b and communication is not reserved.</p>                                                                                                                                                                                                                          |                                             |                                                              |                                                         |                  |         |            |                    |         |         |

### 37.5.9 IICB Low-level Width Setting Register (IICm\_IICB0WL) (m = 0 to 3)

The IICB0WL register sets the low level width of the serial clock signal (SCLm).

*Note:* Writing to the IICB0WL register is prohibited when the IICB0CTL0.IICB0IICE bit = 1b.

**Access Size:** 32 bits

**Address(es):** <IIC0\_S0\_base> + 0024h  
<IIC1\_S0\_base> + 0024h  
<IIC2\_S0\_base> + 0024h  
<IIC3\_S0\_base> + 0024h

**Initial Value:** 0000\_03FFh

|--------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 10     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                                                                                                                       |
| 9 to 0       | IICB0WH[9:0] | Specify the HIGH (high level width of SCLm clock) interval of IIC bus standard.<br>The value of the IICB0WH register is used to determine the serial output timing for other IIC bus standards. |

### 37.5.10.1 Setting the Transfer Clock by the IICB0WL and IICB0WH Registers

The values of the IICB0WL and IICB0WH registers are used to generate various timings in the IIC bus specifications.

#### (1) Setting the transfer clock on the master side

$$\text{Transfer clock (Hz)} = \frac{\text{PCLK}}{\text{IICB0WL} + \text{IICB0WH}} + \text{PCLK} (t_R + t_F)$$

At this time, the appropriate settings of IICB0WL and IICB0WH are as follows.

(All decimal points are rounded up.)

- In high-speed mode

$$\text{IICB0WL} = (0.52 / \text{Transfer clock}) \times \text{PCLK}$$

$$\text{IICB0WH} = (0.48 / \text{Transfer clock} - t_R - t_F) \times \text{PCLK}$$

- In standard mode

$$\text{IICB0WL} = (0.47 / \text{Transfer clock}) \times \text{PCLK}$$

$$\text{IICB0WH} = (0.53 / \text{Transfer clock} - t_R - t_F) \times \text{PCLK}$$

**Note:** Make sure that the data hold time does not exceed 0.9 [μs] in high-speed mode and 3.45 [μs] in standard mode.

#### NOTES

1. The data hold time is as follows depending on the setting of IICWL: Data hold time = IICB0WL[9:2]/PCLK.
2. When performing communications at 400 kbit/s in high-speed mode with PCLK = 100 MHz and  $t_R/t_F$  as 0, the settings are as follows.  
 IICB0WL = 82h  
 IICB0WH = 78h

**(2) Setting IICB0WL and IICB0WH on the slave side**

(All decimal points are rounded up.)

- In high-speed mode

$$\text{IICB0WL} = 1.3 \mu\text{s} \times \text{PCLK} \quad \text{IICB0WH} = (1.2 \mu\text{s} - t_R - t_F) \times \text{PCLK}$$

- In standard mode

$$\text{IICB0WL} = 4.7 \mu\text{s} \times \text{PCLK} \quad \text{IICB0WH} = (5.3 \mu\text{s} - t_R - t_F) \times \text{PCLK}$$

**NOTES**

- 
- IICB0WL: IICB low-level width setting register
  - IICB0WH: IICB high-level width setting register
  - $t_F$ : SDA<sub>n</sub> and SCL<sub>n</sub> signal falling time
  - $t_R$ : SDA<sub>n</sub> and SCL<sub>n</sub> signal rising time
  - PCLK: Clock frequency supplied to this macro
  - $f_{\text{CLK}}$ : SCL clock frequency

37.5.11 IICB Emulation Read Register (IICm\_IICB0EDAT) (m = 0 to 3)

The IICB0EDAT register is used to read the value of the IICB0DAT register.

This register is also initialized by changing the IICB0CTL0.IICB0IICE bit from 1b to 0b and the IICB0CTL0.IICB0IICE bit from 0b to 1b.

|                |    |                        |    |    |    |    |    |    |                |    |    |    |    |    |    |    |  |
|----------------|----|------------------------|----|----|----|----|----|----|----------------|----|----|----|----|----|----|----|--|
| Access Size:   |    | 32 bits                |    |    |    |    |    |    |                |    |    |    |    |    |    |    |  |

Table 37.5-12 IICm\_IICB0DATS Register Contents

| Bit Position | Bit Name        | Description                                                              |
|--------------|-----------------|--------------------------------------------------------------------------|
| 31 to 8      | —               | Reserved. These bits are read as 0b.                                     |
| 7 to 0       | IICB0DATS [7:0] | Indicates the value of the shift register that stores the transfer data. |

Note: The shift register is a register that holds the data received from SDAI during reception and shifts the data transferred from the IICB0DAT register during transmission.

## 37.6 Operation

This IIC bus is used for master and slave operations through the IIC bus.

This IIC bus is a serial bus for multiple masters. It has a clocked serial I/C format with the function for bus configuration so that communications with multiple devices can proceed with the two signal lines, the serial clock (SCL) and serial data bus (SDA). Therefore, when configuring the serial bus with multiple microcontrollers and peripheral ICs, reducing the number of ports to be used and wirings on the board is possible.

The master is able to output a start condition, slave address, data, and stop condition to a slave.

The slave automatically detects these received data by hardware. This function makes it possible to simplify the IIC bus control section in the application program.

In the IIC bus, the serial clock pin (SCL) and serial data bus pin (SDA) are open-drain outputs, so the serial clock line and serial data bus line require pull-up resistors.

The prefix (IICm\_) of the register names is omitted in this and subsequent sections.

### 37.6.1 IIC Bus Functions

For the functions of the IIC bus, refer to THE I2C-BUS SPECIFICATION VERSION 2.1 issued by Philips Semiconductors in January 2000.

The following describes the functions of the IIC Bus.

#### 37.6.1.1 Communications Mode

Standard mode (transfer speed: up to 100 kbits/s) and fast mode (transfer speed: up to 400 kbits/s) are supported. High-speed mode (transfer speed: up to 3400 kbits/s) is not supported.

#### 37.6.1.2 Automatic Detection of Serial Data

A start condition, slave address, data, and stop condition on the serial data bus are automatically detected.

#### 37.6.1.3 Chip Selection by Address

By transmitting the slave address or extension code in master operation, the specific slave address connected to the IIC bus can be selected for communications.

#### 37.6.1.4 Wakeup Function

In slave operation, an interrupt only occurs when the received address matches the value of the slave address register (SVA0) and the extension code is received. Accordingly, the CPU other than the selected slave on the IIC bus can operate regardless of serial communications.

#### **37.6.1.5 Acknowledge (ACK) Control**

In master/slave operation, an acknowledge signal to check the normal execution of serial communications can be controlled.

#### **37.6.1.6 Wait (WAIT) Control**

A wait signal to notify the wait state can be controlled.

#### **37.6.1.7 Arbitration Control**

When multiple masters generate a start condition at the same time, the IIC bus is able to compare the level on the serial data bus (SDA) pin after the adjustment of synchronization with the serial clock (SCL) to finally select the master.

#### **37.6.1.8 Continuous Transfer**

When ACK for the transmitted data is received at the low level, the data can be transmitted continuously.

In addition, ACK for the received data is transmitted at the low level, the data can be received continuously.

### 37.6.2 Definition of the IIC Bus

The following describes the serial data communications format of the IIC bus and the meaning of the signals to be used.

The figure below shows the timing of transfer of a “start condition”, “address”, “transfer direction specification”, “data”, and “stop condition”, which are generated on the serial data bus of the IIC bus.

Figure 37.6-1 IIC Serial Data Transfer Timing

The start condition, slave address, and stop condition are generated by the master. An acknowledge ( $\overline{\text{ACK}}$ ) can be generated by either the master or slave (it is usually generated by the receiver of 8-bit data).

The serial clock (SCLm) is continuously output by the master. The slave is able to extend the low-level period of the SCLm pin and insert a wait.

#### 37.6.2.1 Start Condition

A start condition is met when the SDAm pin changes from the high to the low level while the SCLm pin is at the high level. A start condition is generated when the master starts serial transfer to the slave. When the IIC is used as a slave, the start condition can be detected.

Figure 37.6-2 Start Condition

### 37.6.2.2 Address

7-bit data following the start condition are defined as an address.

An address is a 7-bit data segment that is output in order for the master to select the specific slave from among multiple slaves that are connected to the bus lines. Accordingly, all slaves on the bus lines must have different addresses.

A slave checks whether the 7-bit data matches its own address. At this time, matching with its own address means that this slave is selected, and after that it communicates with the master until the master generates a start condition or stop condition.

Figure 37.6-3 Address

### 37.6.2.3 Extention Code

When the higher-order four bits of the address are 0000 or 1111, these bits are called extension code. **Table 37.6-1** lists the definitions of bits as extension code.

Table 37.6-1 Extension Code Bit Definitions

| Slave Address | R/W Bit | Description                                 |
|---------------|---------|---------------------------------------------|
| 0000 000b     | 0b      | General call address                        |
| 0000 000b     | 1b      | Start byte                                  |
| 0000 001b     | x       | CBUS address                                |
| 0000 010b     | x       | Address reserved for a different bus format |
| 0000 011b     | x       | Reserved for future use                     |
| 0000 1xxb     | x       | HS mode master code*1                       |
| 1111 0xxb     | x       | 10-bit slave address specification          |
| 1111 1xxb     | x       | Reserved for future use                     |

Note 1. HS mode cannot be used in this unit.

Note 2. x : Don't care

### 37.6.2.4 Transfer Direction Specification

The master transmits 1-bit data to specify the transfer direction following the 7 address bits. The value of this transfer direction specification bit being 0b indicates that the master transmits data to the slave. The value 1b indicates that the master receives data from the slave.

Figure 37.6-4 Transfer Direction Specification

### 37.6.2.5 Acknowledge

1-bit data following the transfer direction bit ( $\overline{R/W}$ ) for address transfer and 1-bit data following 8-bit data are defined as acknowledge.

The acknowledge allows checking the state of serial data in the transmitter and receiver. The acknowledge being returned at the low level is called ( $\overline{ACK}$ ), which indicates normal end. The acknowledge being returned at the high level is called (NACK), which indicates abnormal end.

The receiver returns an acknowledge every time it receives 8-bit data.

The transmitter usually receives an acknowledge following the transmission of 8-bit data. When ( $\overline{ACK}$ ) is returned from the receiver, the transmitter recognizes that reception has proceeded correctly and continues processing.

When the master receives the last of data in reception, it does not return an acknowledge but generates a stop condition.

When the slave returns (NACK) in reception, the master generates a stop condition or restart condition to stop transmission. If (NACK) is returned, the following causes can be considered:

- 1) Reception has not proceeded correctly.
- 2) Reception of the last of data has ended.
- 3) The receiver specified by the address is not present.

Figure 37.6-5 Acknowledge ( $\overline{ACK}$ )

### 37.6.2.6 Data

Bits, except for 9 bits following the start condition (address (7 bits),  $\overline{R/W}$  (1 bit), and acknowledge (1 bit)) and the acknowledge, are defined as data.

If a 10-bit address is specified with the use of the extension code, 8-bit data following address transfer are used as the address (second address).

### 37.6.2.7 Stop Condition

A stop condition is met when the SDA<sub>m</sub> pin changes from the low to the high level while the SCL<sub>m</sub> pin is at the high level.

A stop condition is generated when the master has completed serial transfer to the slave.

Figure 37.6-6 Stop Condition

### 37.6.2.8 Wait

A wait notifies the other party that the master or slave is preparing to transmit or receive data (i.e., in the wait state).

By driving the SCLm pin to the low level, the other party is notified of the wait state. When both the master and slave are released from the wait state, a next data transfer can be started.

Figure 37.6-7 Wait (1/2)

(b) When both the master and slave enter the wait state in the 9th clock cycle (master: for transmission, slave: for reception)

Figure 37.6-7 Wait (2/2)

### 37.6.2.9 Arbitration

When multiple masters generate a start condition at the same time, master communications proceed while adjusting the clock cycles until the data differ from one another. The following describes an example where two masters generate a start condition at the same time and arbitration occurs.

Here, suppose that a master that outputs the high level to the SDAm line (master 1) and a master that outputs the low level to the SDAm line (master 2) are present when the SCLm line is at the low level.

In this case, communications by the master that has output the low level to the SDAm line are given priority and communications are not permitted for the master that has output the high level to the SDAm line.

Such procedure is called arbitration and the state in which communications are not permitted is called arbitration loss.

The master that has lost in arbitration releases the bus by placing both the SCLm and SDAm lines in the high-impedance state at the time it lost in arbitration.

Figure 37.6-8 Example Timing of Arbitration

37.6.3 Operations for Communications

This unit supports single transfer mode and continuous transfer mode as the transfer mode.

The transfer mode when the address matches between the master and slave is selected by the IICB0CTL0.IICB0MDTX0 bit, and the transfer mode when the extension code is detected by the slave is selected by the IICB0CTL0.IICB0MDTX1 bit.

37.6.3.1 Single Transfer Mode

In single transfer mode, a data transmission/reception interrupt request signal (IICBTIA) is generated to place the IIC in the wait state with the timing set in the IICB0CTL0.IICB0SLWT bit and data to be transferred are processed during this wait period.

Operations for each processing are described below.

(1) Example of Communications in Single Transfer Mode (Master Reception)

<1> Start condition output

Set the IICB0TRG.IICB0STT bit to 1.

- <2> Address and transfer direction specification output  
Set the combination of the slave's address and transfer direction as 8 bits in the IICB0DAT register.
- <3> Checking the acknowledge result  
Check the result by reading the IICB0STR0.IICB0SSAC bit in response to the IICBTIA interrupt.
- <4> Wait timing setting  
In data reception, clear the IICB0CTL0.IICB0SLWT bit to 0b to place the IIC in the wait state on the rising edge of the 8th clock cycle.
- <5> Data reception  
Set the IICB0TRG.IICB0WRET bit to 1b during the wait period to release the wait state and start reception.
- <6> Loading received data  
Read the received data from the IICB0DAT register in response to the IICBTIA interrupt.
- <7> Data reception completion processing
- Set the IICB0CTL0.IICB0SLWT bit to 1 and the IICB0CTL0.IICB0SLAC bit to 0b during the wait period.
  - After that, set the IICB0TRG.IICB0WRET bit to 1b to release the wait state. An acknowledge is not generated and the transmitter is notified of the end of the data.
- <8> Stop condition output  
Set the IICB0TRG.IICB0SPT bit to 1b.

**(2) Example of Communications in Single Transfer Mode (Master Transmission)****<1> Start condition output**

Set the IICB0TRG.IICB0STT bit to 1b.

**<2> Address and transfer direction specification output**

Set the combination of the slave's address and transfer direction as 8 bits in the IICB0DAT register.

**<3> Checking the acknowledge result**

Check the result by reading the IICB0STR0.IICB0SSAC bit in response to the IICBTIA interrupt.

**<4> Data transmission**

Set the data for transmission in the IICB0DAT register during the wait period to release the wait state and start transmission.

**<5> Stop condition output**

Set the IICB0TRG.IICB0SPT bit to 1b.

NOTE

In data transmission, set the IICB0CTL0.IICB0SLWT bit to 1 to place the IIC in the wait state on the falling edge of the 9th clock cycle.

### (3) Example of Communications in Single Transfer Mode (Slave Reception)

- <1> Checking the operating mode in slave operation
  - Check the operating mode in response to the IICBTIA interrupt.
  - Check the address transfer, address match, and that operation is for reception by reading the IICB0STR0.IICB0SSST, IICB0STR0.IICB0SSCO, and IICB0STR0.IICB0SSTR bits.
  - Read the IICB0DAT register (empty reading).

- ## <2> Wait timing setting

In data reception, clear the IICB0CTL0.IICB0SLWT bit to 0 to place the IIC in the wait state on the falling edge of the 8th clock cycle.

## &lt;3&gt; Data reception

Set the IICB0TRG.IICB0WRET bit to 1b during the wait period to release the wait state and start reception.

## &lt;4&gt; Loading received data

Read the received data from the IICB0DAT register in response to the IICBTIA interrupt.

## &lt;5&gt; Data reception completion processing

- Set the IICB0CTL0.IICB0SLWT bit to 1b and the IICB0CTL0.IICB0SLAC bit to 0b during the wait period.
- After that, set the IICB0TRG.IICB0WRET bit to 1b to release the wait state. An acknowledge is not generated and the transmitter is notified of the end of the data.

## &lt;6&gt; Stop condition detection

A stop condition is detected in response to the IICBTIS interrupt.

**(4) Example of Communications in Single Transfer Mode (Slave Transmission)****<1> Checking the operating mode in slave operation**

- Check the operating mode in response to the IICBTIA interrupt.
- Check the address transfer, address match, and that operation is for transmission by reading the IICB0STR0.IICB0SSST, IICB0STR0.IICB0SSCO, and IICB0STR0.IICB0SSTR bits.
- Read the IICB0DAT register (empty reading).

**<2> Data transmission**

Set the data for transmission in the IICB0DAT register during the wait period to release the wait state and start transmission.

**<3> Checking the acknowledge result**

Check the result by reading the IICB0STR0.IICB0SSAC bit in response to the IICBTIA interrupt.

If an acknowledge is not generated, the transmission is judged to have been completed, and the IIC is released from the wait state by setting the IICB0TRG.IICB0WRET bit to 1b.

**<4> Stop condition detection**

A stop condition is detected in response to the IICBTIS interrupt.

### 37.6.3.2 Continuous Transfer Mode

In continuous transfer mode, data can be transferred continuously without the IIC being placed in the wait state by reading from or writing to the IICB0DAT register every time a data transmission/reception interrupt request signal (IICBTIA) is generated.

Operations for each processing are described below.

#### (1) Example of Communicaitons in Continuous Transfer Mode (Master Reception)

#### <1> Start condition output

Set the IICB0TRG.IICB0STT bit to 1b.

#### <2> Address and transfer direction specification output

Set the combination of the slave's address and transfer direction as 8 bits in the IICB0DAT register.

#### <3> Checking the acknowledge result

The IICBTIS interrupt only occurs when the slave does not return the acknowledge.

Check the result by reading the IICB0STR0.IICB0SSAC bit.

## &lt;4&gt; Checking the acknowledge result

If the IICB0DAT register has no unread data by the time reception starts, the IIC is not placed in the wait state and reception starts.

## &lt;5&gt; Loading received data

Read the received data from the IICB0DAT register in response to the IICBTIA interrupt.

## &lt;6&gt; Data reception completion processing

By clearing the IICB0CTL0.IICB0SLAC bit to 0b before reading the previous received data before the final received data, a next acknowledge is not generated and the transmitter is notified of the end of the data.

## &lt;7&gt; Stop condition output

Set the IICB0TRG.IICB0SPT bit to 1b.

## (2) Example of Communications in Continuous Transfer Mode (Master Transmission)

## &lt;1&gt; Start condition output

Set the IICB0TRG.IICB0STT bit to 1b.

## &lt;2&gt; Address and transfer direction specification output

Set the combination of the slave's address and transfer direction as 8 bits in the IICB0DAT register.

## &lt;3&gt; Data transmission

Set the data for transmission in the IICB0DAT register in response to the IICBTIA interrupt.

## &lt;4&gt; Checking the acknowledge result

The IICBTIS interrupt only occurs when the slave does not return the acknowledge.

Check the result by reading the IICB0STR0.IICB0SSAC bit.

## &lt;5&gt; Stop condition output

Set the IICB0TRG.IICB0SPT bit to 1b.

**(3) Example of Communications in Continuous Transfer Mode (Slave Reception)**

## &lt;1&gt; Data reception

If the IICB0DAT register has no unread data by the time reception starts, the IIC is not placed in the wait state and reception starts.

## &lt;2&gt; Checking the operating mode in slave operation

- Check the operating mode in response to the IICBTIS interrupt.
- Check the address transfer, address match, and that operation is for reception by reading the IICB0STR0.IICB0SSST, IICB0STR0.IICB0SSCO, and IICB0STR0.IICB0SSTR bits.
- Read the IICB0DAT register (empty reading).

## &lt;3&gt; Loading received data

Read the received data from the IICB0DAT register in response to the IICBTIA interrupt.

## &lt;4&gt; Data reception completion processing (1)

By clearing the IICB0CTL0.IICB0SLAC bit to 0b before reading the previous received data before the final received data, a next acknowledge is not generated and the transmitter is notified of the end of the data.

## &lt;5&gt; Data reception completion processing (2)

The IICBTIS interrupt only occurs when the slave does not return the acknowledge.

The IIC is released from the wait state by setting the IICB0TRG.IICB0WRET bit to 1b.

## &lt;6&gt; Stop condition detection

A stop condition is detected in response to the IICBTIS interrupt.

**(4) Slave Transmission in Continuous Transfer Mode**

## &lt;1&gt; Checking the operating mode in slave operation

- Check the operating mode in response to the IICBTIS interrupt.
- Check the address transfer, address match, and that operation is for transmission by reading the IICB0STR0.IICB0SSST, IICB0STR0.IICB0SSCO, and IICB0STR0.IICB0SSTR bits.
- After reading the IICB0DAT register (empty reading), set the first data for transmission in the IICB0DAT register.

## &lt;2&gt; Data transmission

Set the data for transmission in the IICB0DAT register in response to the IICBTIA interrupt.

## &lt;3&gt; Checking the acknowledge result

The IICBTIS interrupt only occurs when the slave does not return the acknowledge.

Check the result by reading the IICB0STR0.IICB0SSAC bit.

If an acknowledge is not generated, the transmission is judged to have been completed, and the IIC is released from the wait state by setting the IICB0TRG.IICB0WRET bit to 1b.

## &lt;4&gt; Stop condition detection

A stop condition is detected in response to the IICBTIS interrupt.

37.6.3.3 Processing of Final Data in Continuous Transfer Mode

The following describes operations for processing of final data when operation is in continuous transfer mode in the case of transmission and reception, respectively.

(1) Processing of Final Data in Reception

While operation is for reception, write 0b to ICB0SLAC before reading the previous received data before the final received data (reading IICB0DAT).

When the falling edge of the 8th clock cycle of SCLI is detected, the IIC judges whether the data received in the previous communications have been read.

If the data have been read, the IIC transmits the ACK bit in accord with the value of the IICB0SLAC bit at this time (on detection of the falling edge of the 8th clock cycle of SCLI) and is placed in the wait state if the data have not been read. When the data have been read from the IICB0DAT register, the IIC transmits the ACK bit in accord with the value of the IICB0SLAC bit.

Figure 37.6-9 is a timing chart of the example of final data processing in the case of reception.

Figure 37.6-9 Processing of Final Data in Reception

## (2) Processing of Final Data in Transmission

During the transmission operation, processing of final data differs in master operation and slave operation. The following describes operations for processing of final data in the case of master operation and slave operation.

### < In master operation >

In master operation, a restart or stop condition is issued after the completion of transmission of the final data by writing 1b to IICB0STT or IICB0SPT after the IICBTIA interrupt following writing of the final data (with the timing of \*<sup>1</sup> in **Figure 37.6-10** when a restart or stop condition is set).

Even when writing of 1b to IICB0STT or IICB0SPT is delayed, the IIC is placed in the wait state (if data have not been written to IICB0DAT), so IICB0STT and IICB0SPT can be set to 1b. If 1b is written to IICB0STT at this time, subsequent writing to IICB0DAT is possible.

**Figure 37.6-10** shows the operations for final data processing in the case of master operation.

Figure 37.6-10 Operations for Final Data Processing in Transmission (IICB0SSMS = 1b & Continuous Transfer Mode)

When both writing 1 to IICB0STT and writing 1b to IICB0SPT proceed in the interval (1) in **Figure 37.6-10**, the subsequent setting is enabled and the previous setting is disabled.

Similarly, writing to IICB0DAT before writing 1b to IICB0STT (or to IICB0SPT) is ignored in the interval (1). The data written to IICB0DAT after 1b has been written to IICB0STT are transmitted as the data following the output of a start condition (the address).

**< In slave operation >**

In slave operation, the (external) master determines the final data. Accordingly, the data must always be transmitted (written to IICB0DAT) when ACK is received by the (external) master.

**CAUTION**

---

Even if there are no data for transmission, write any data to IICB0DAT. If writing to IICB0DAT does not proceed, bus communications may be stopped because the unit retains its state while in the wait state.

---

### 37.6.3.4 Arbitration

When multiple masters generate a start condition at the same time, master communications proceed while adjusting the clock cycles until the data differ from one another. **Figure 37.6-11** shows an example where two masters output a start condition at the same time and arbitration occurs.

Here, suppose that a master which outputs the high level to the SDA line (master 1) and a master which outputs the low level to the SDA line (master 2) are present when the SCL line is at the low level.

In this case, communications by the master which outputs the low level to the SDA line (master 2) are given priority, and communications are not permitted for the master which outputs the high level to the SDA line (master 1). Such procedure is called arbitration and the state where communications are not permitted is called arbitration loss.

Figure 37.6-11 Example of Arbitration Loss

When this unit detects an arbitration loss in the master, it drives SCLm and SDAm to the high level respectively to place the slave in the standby state, and sets the IICB0STR0.IICB0ALDF bit to 1b at the time a status interrupt request signal (IICBTIS) is subsequently generated.

#### (1) State when Arbitration Occurs

The following describes the states in which arbitration occurs in master operation (the IICB0STR0.IICB0SSMS bit = 1b).

- 1) Address transmission is in progress.
- 2) Transmission of R/W bits for address transfer is in progress.
- 3) Transmission of the extension code is in progress.
- 4) Transmission of  $\overline{R/W}$  bits for extension code transfer is in progress.
- 5) Data transmission is in progress.
- 6) Transmission of the  $\overline{ACK}$  bit after data reception is in progress.
- 7) The start condition is detected while address transfer or data transfer is in progress.

- 8) The stop condition is detected while address transfer or data transfer is in progress.
- 9) The SDA pin remains at the low level though generation of a restart condition is attempted.
- 10) The SDA pin remains at the low level though generation of a stop condition is attempted.
- 11) A falling edge of the SCL pin is detected though generation of a restart condition is attempted.

## (2) Arbitration Checking Period and Judging Arbitration Loss

The following describes the states from (1) to (11) described in **Section 37.6.3.4(1), State when Arbitration Occurs**.

In (1) to (6), SDAO and SDAI are compared when a rising edge of SCL is detected, and if SDAO = "H" & SDAI = "L", this is judged to be an arbitration loss.

In (7), arbitration is checked all through the period while IICB0SSMS = 1b. In the checking period, detection of the start condition that is not output by itself is judged to be an arbitration loss.

In (8), arbitration is checked all through the period while IICB0SSMS = 1b. In the checking period, detection of the stop condition that is not output by itself is judged to be an arbitration loss.

**Figure 37.6-12** shows the checking range from (1) to (8).

Figure 37.6-12 Arbitration Checking Range (from (1) to (8))

In (9), after writing 1 to IICB0STT, arbitration is checked when the first rising edge of SCL1 is detected while the output of a restart condition is being prepared. If SDAI = “L” at this time, this is judged to be an arbitration loss.

**Figure 37.6-13** shows the arbitration-lost state in (9).

Figure 37.6-13 Arbitration-Lost State in (9)

In (10), after writing 1 to IICB0SPT, arbitration is checked when the first falling edge of SCL1 after the output of a stop condition is detected. When the stop condition is not detected by the time the falling edge of SCL1 is detected, this is judged to be an arbitration loss. **Figure 37.6-14** shows the arbitration-lost state.

Figure 37.6-14 Arbitration-Lost State in (10)

In (11), after writing 1 to IICB0STT, arbitration is checked when the first falling edge of SCLI is detected while the output of a restart condition is being prepared. When the restart condition is not detected by the time the falling edge of SCLI is detected, this is judged to be an arbitration loss. **Figure 37.6-15** shows the arbitration-lost state.

Figure 37.6-15 Arbitration-Lost State in (11)

### 37.6.3.5 Procedure for Transition to and Release from the Wait State

This unit can be placed in the wait state with the timing shown below.

Table 37.6-2 Timing of Transition to the Wait State

| Generation Timing | Description                                                                                                                      | Reference                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| △ 0               | Detection of the first falling edge of SCLm after detection of the start condition as the master                                 | <b>Section 37.6.3.5(1), Wait State on the First Falling Edge of SCLm as the Master</b>                   |
| △ 1               | Detection of the falling edge of the 9th clock cycle of SCLm while address transfer following the start condition is in progress | <b>Section 37.6.3.5(2), Wait State on Completion of Address Transfer</b>                                 |
| △ 2               | Detection of the falling edge of 8th clock cycle of SCLm while data transfer is in progress                                      | <b>Section 37.6.3.5(3), Wait State on Detection of the 8th Falling Edge of SCLm during Data Transfer</b> |
| △ 3               | Detection of the falling edge of 9th clock cycle of SCLm while data transfer is in progress                                      | <b>Section 37.6.3.5(4), Wait State on Detection of the 9th Falling Edge of SCLm during Data Transfer</b> |

**Note:** ST: Start condition  
AD6-AD0: Address  
R/W: Transfer direction specification  
ACK: Acknowledge  
D7-D0: Data  
SP: Stop condition

The procedure for release from the wait state depends on the state of waiting.

Release the wait state according to the release conditions for the respective wait states described in **Section 37.6.3.5(1)** to **Section 37.6.3.5(4)**.

### (1) Wait State on the First Falling Edge of SCLm as the Master

$\Delta 0$  is a wait state in the case where the data to be transferred have not been written to the IICB0DAT register when the first falling edge of SCLm as the master is detected after writing 1 to the IICB0TRG.IICB0STT bit.

#### (a) Condition for Transition to the Wait State

After writing 1b to the IICB0TRG.IICB0STT bit, the IIC is placed in the wait state on detection of the first falling edge of SCLm as the master if writing to the IICB0DAT register has not proceeded by the time of  $\Delta 0$  after writing 1b to the IICB0TRG.IICB0STT bit.

However, the timing at which effective writing to the IICB0DAT register can proceed (without a wait) after writing 1b to the IICB0TRG.IICB0STT bit differs between when the communication reservation function is permitted and when this function is prohibited. **Figure 37.6-16** shows the timing of effective writing to the IICB0DAT register with the respective settings.

Figure 37.6-16 Timing of Effective Writing to the IICB0DAT Register

#### (b) Condition for Release from the Wait State

Release the wait state by writing to the IICB0DAT register.

## (2) Wait State on Completion of Address Transfer

△ 1 is a wait state on completion of address transfer.

### (a) Condition for Transition to the Wait State

#### < Single transfer mode >

In single transfer mode, the IIC is always placed in the wait state in master operation. In slave operation, it is placed in the wait state in response to an address match or the extension code being detected and when the IICB0CTL0.IICB0SLWT bit = 1b.

#### < Continuous transfer mode >

In continuous transfer mode, the IIC is placed in the wait state in any of the following cases.

- NACK being detected.
- In master transmission, the next data for transfer not having been written.
- In slave operation, the previous received data not having been read or operation is for transmission.

### (b) Condition for Release from the Wait State

#### < Single transfer mode >

Release the wait state by writing to the IICB0DAT register in transmission and by writing 1b to the IICB0TRG.IICB0WRET bit in reception. In master operation, if the IICB0STR0.IICB0SSAC bit = 0b and operation is for transmission, releasing the wait state is possible by writing 1 to the IICB0TRG.IICB0STT or IICB0TRG.IICB0SPT bit.

#### < Continuous transfer mode >

Release the wait state by writing to the IICB0DAT register in transmission and by reading the IICB0DAT register in reception. In master operation, if the IICB0STR0.IICB0SSAC bit = 0b, releasing the wait state is possible by writing 1b to the IICB0TRG.IICB0STT or IICB0TRG.IICB0SPT bit.

**(3) Wait State on Detection of the 8th Falling Edge of SCLm during Data Transfer**

△ 2 is a wait state on detection of the 8th falling edge of SCLm during data transfer.

**(a) Condition for Transition to the Wait State****< Single transfer mode >**

When the IICB0CTL0.IICB0SLWT bit = 0 while the IIC participates in communications, the IIC is placed in the wait state on detection of the 8th falling edge of SCLm.

**< Continuous transfer mode >**

When the IICB0STR0.IICB0SSTR bit = 0b while the IIC participates in communications, the IIC is placed in the wait state if processing of the previous data (reading from the IICB0DAT register) has not proceeded and 1b has not been written to the IICB0TRG.IICB0STT or IICB0TRG.IICB0SPT bit before the 8th falling edge of SCLm.

**(b) Condition for Release from the Wait State****< Single transfer mode >**

Release the wait state by writing 1b to IICB0TRG.IICB0WRET in reception and by writing to the IICB0DAT register in transmission.

**< Continuous transfer mode >**

Release the wait state by reading the IICB0DAT register.

#### (4) Wait State on Detection of the 9th Falling Edge of SCLm during Data Transfer

△3 is a wait state on detection of the 9th falling edge of SCLm during data transfer. In continuous transfer mode, the IIC is placed in the wait state on reception of NACK.

##### (a) Condition for Transition to the Wait State

###### < Single transfer mode >

When the IICB0CTL0.IICB0SLWT bit = 1 while the IIC participates in communications, the IIC is placed in the wait state on detection of the 9th falling edge of SCLm.

###### < Continuous transfer mode >

The IIC is placed in the wait state in any of the following states (when it participates in communications in all cases) during data transmission.

- NACK being received in the  $\overline{\text{ACK}}$  bit while the IICB0CTL0.IICB0SLWT bit = 1b.
- In transmission, the data for transmission not having been written to the data register.
- In reception, the previous received data not having been read.

##### (b) Condition for Release from the Wait State

Table 37.6-3 lists the conditions for release from the wait state in each mode.

Table 37.6-3 Conditions for Release from the Wait State

| Master/Slave | Transfer Mode            | Transmission/<br>Reception | IICB0STR0.<br>IICB0SSAC Bit | Release Operation                                                                                  |
|--------------|--------------------------|----------------------------|-----------------------------|----------------------------------------------------------------------------------------------------|
| Master       | Single transfer mode     | Reception                  | 0b                          | IICB0TRG.IICB0STT bit = 1b or<br>IICB0TRG.IICB0SPT bit = 1b                                        |
|              |                          |                            | 1b                          | IICB0TRG.IICB0WRET = 1b                                                                            |
|              |                          | Transmission               | 0b                          | IICB0TRG.IICB0STT bit = 1b or<br>IICB0TRG.IICB0SPT bit = 1b                                        |
|              |                          |                            | 1b                          | Writing to the IICB0DAT register or<br>IICB0TRG.IICB0STT bit = 1b or<br>IICB0TRG.IICB0SPT bit = 1b |
|              | Continuous transfer mode | Reception                  | 0b                          | IICB0TRG.IICB0STT bit = 1b or<br>IICB0TRG.IICB0SPT bit = 1b                                        |
|              |                          |                            | 1b                          | Reading from the ICBnDAT register*1                                                                |
|              |                          | Transmission               | 0b                          | IICB0TRG.IICB0STT bit = 1b or<br>IICB0TRG.IICB0SPT bit = 1b                                        |
|              |                          |                            | 1b                          | Writing to the IICB0DAT register*2                                                                 |
| Slave        | Single transfer mode     | Reception                  | —                           | IICB0TRG.IICB0WRET bit = 1b                                                                        |
|              |                          | Transmission               | 0b                          | IICB0TRG.IICB0WRET bit = 1b                                                                        |
|              |                          |                            | 1b                          | Writing to the IICB0DAT register*1                                                                 |
|              | Continuous transfer mode | Reception                  | 0b                          | IICB0TRG.IICB0WRET bit = 1b                                                                        |
|              |                          | Transmission               | 0b                          | IICB0TRG.IICB0WRET bit = 1b                                                                        |
|              |                          |                            | 1b                          | Writing to the IICB0DAT register                                                                   |

Note 1. The condition for release from the wait state due to the data for transmission not having been written to the data register.

Note 2. The condition for release from the wait state due to the previous received data not having been read.

### 37.6.3.6 Extension Code

The processing when the extension code is received differs with the data following the extension code, so this processing must be handled by the user's software processing.

Therefore, the operation differs from that at the time of normal slave address reception. The differences are as follows.

- (1) When the higher-order 4 bits of the received address are 0000 or 1111, the extension code reception flag (IICB0STR0.IICB0SSEX bit) is set to indicate the reception of the extension code, and a status interrupt request signal (IICBTIS) is generated on the falling edge of the 8th clock cycle, and then the IIC is placed in the wait state (ICB0TRG.IICB0SSWT = 1b).  
Also, the IICB0STR0.IICB0SSDR and IICB0STR0.IICB0SSTR bits are set to 1b.
- (2) In the output of the acknowledge during address transfer, the acknowledge can be controlled by the setting of the IICB0CTL0.IICB0SLAC bit. During address transfer at the time of normal slave address reception, the acknowledge is output when the addresses match, regardless of the setting of IICB0CTL0.IICB0SLAC.
- (3) The procedure for release from the wait state on detection of the extension code is as follows.
  - When the IICB0CTL0.IICB0MDTX1 bit = 0b  
In the case of transmission while the IICB0CTL0.IICB0SLWT bit = 0b, release the wait state by writing to the IICB0DAT register. In the case of transmission while the IICB0CTL0.IICB0SLWT bit = 1b or in the case of reception, release the wait state by writing 1b to the IICB0TRG.IICB0WRET bit.
  - When the IICB0CTL0.IICB0MDTX1 bit = 1b  
Release the wait state by writing to the IICB0DAT register in transmission and by reading the IICB0DAT register in reception.
- (4) On the falling edge of the 9th clock cycle after that, an interrupt request signal (IICBTIA) is generated and the IIC is placed in the wait state (the IICB0TRG.IICB0SSWT bit = 1b) if the IICB0CTL0.IICB0SLWT bit = 1b. If the IICB0CTL0.IICB0SLWT bit = 0b, an interrupt request signal (IICBTIA) is not generated and the IIC is not placed in the wait state.
- (5) When the IIC receives the extension code, it participates in communications even if the addresses do not match. For example, when the IIC is not to operate as a slave after the reception of the extension code, set the IICB0TRG.IICB0LRET bit to 1b. The IIC is placed in the standby state for the next communications.

## 37.7 Interrupts

### 37.7.1 Interrupt Request Signal

#### **CAUTION**

---

The operation when receiving an extension code is omitted from the description. For details, see **Section, 37.6.2.3, Extension Code**.

---

This unit has two interrupt request signals: a data transmission/reception interrupt request signal (IICBTIA) and a status interrupt request signal (IICBTIS). The timing of the interrupt request signal generation differs depending on the transfer mode set in the IICB0CTL0.IICB0MDTX1 and IICB0CTL0.IICB0MDTX0 bits. In this section, the respective interrupt request signals are explained for different transfer modes.

For the selection of single transfer mode or continuous transfer mode, the IICB0CTL0.IICB0MDTX0 bit is used for transfer on an address match between the master and slave, and the IICB0CTL0.IICB0MDTX1 bit is used for transfer on detection of the extension code by the slave.

### 37.7.1.1 Single Transfer Mode

The table below shows the interrupt request signal generation timing in the single transfer mode.

In single transfer mode, with the IICBTIA interrupt request signal and the IICBTIS interrupt request signal, whether to generate an interrupt is judged based on the status of this unit when the SCLm falling edge of the bus cycle is detected. However, only in the case of the  $\Delta 4$  timing, whether to generate an interrupt is judged based on the status of the unit when the stop condition is detected.

Table 37.7-1 Interrupt Request Signal Generation Timing (Single Transfer Mode)

| Generation Timing | Description                                                                        | Reference                                                                                                                                             |

| 1b            | 0b            | x             | x             | IICBTIA                     | Wait | —                                                              |
| 1b            | 1b            | x             | x             | There is no such condition. |      | —                                                              |
| 0b            | 0b            | x             | 0b            | IICBTIS*1                   | —    | Non-participation in communications after restart              |
| 0b            | 0b            | x             | 1b            | IICBTIA <sub>n</sub>        | Wait | —                                                              |
| 0b            | 1b            | x             | 0b            | IICBTIS                     | —    | Non-participation in communications after the arbitration loss |
| 0b            | 1b            | x             | 1b            | IICBTIA                     | Wait | —                                                              |

**Note:** x: Don't care

Note 1. An address match or extension code is detected before the restart condition.

### (2) Conditions for Generating Interrupt Request Signals during Data Transfer and Interrupt Request Signals Generated

Δ2 and Δ3 in **Table 37.7-1** are the timing of interrupt request signal generation during data transfer. The timing of the interrupt request signal generation at Δ2 or Δ3 is determined by the setting of the IICB0CTL0.IICB0SLWT bit. **Table 37.7-3** lists the conditions for generating interrupt request signals at the Δ2 and Δ3 timing and the interrupt request signals (IICBTIA or IICBTIS) that are generated.

Table 37.7-3 Conditions for Generating Interrupt Request Signals during Data Transfer and Interrupt Request Signals to be Generated (Single Transfer Mode)

| IICB0<br>SSMS | IICB0<br>ALDF | IICB0<br>SLWT | IICB0<br>SSCO | Δ2                          |      | Δ3        |      | Remarks                                                        |
|---------------|---------------|---------------|---------------|-----------------------------|------|-----------|------|----------------------------------------------------------------|
|               |               |               |               | Interrupt                   | Wait | Interrupt | Wait |                                                                |
| 1b            | 0b            | 0b            | x             | IICBTIA                     | Wait | —         | —    | —                                                              |
| 1b            | 0b            | 1b            | x             | —                           | —    | IICBTIA   | Wait | —                                                              |
| 1b            | 1b            | x             | x             | There is no such condition. |      |           |      | —                                                              |
| 0b            | 0b            | x             | 0b            | —                           | —    | —         | —    | Non-participation in communications                            |

| 0b            | 0b            | 1b            | 1b            | —                           | —    | IICBTIA   | Wait | —                                                              |
| 0b            | 1b            | 0b            | 0b            | IICBITS <sub>n</sub>        | —    | —         | —    | Non-participation in communications after the arbitration loss |
| 0b            | 1b            | 1b            | 0b            | —                           | —    | IICBTIS   | —    | Non-participation in communications after the arbitration loss |
| 0b            | 1b            | 0b            | 1b            | IICBTIA                     | Wait | —         | —    | —                                                              |
| 0b            | 1b            | 1b            | 1b            | —                           | —    | IICBTIA   | Wait | —                                                              |

**Note:** x: Don't care

**(3) Interrupt Request Signal Generation when Stop Condition is Detected**

△4 in **Table 37.7-1** is the timing of interrupt request signal generation when a stop condition is detected.

When the stop condition is detected, the interrupt request signal generation is controlled by setting the IICB0CTL0.IICB0SLSI bit. When the IICB0CTL0.IICB0SLSI bit is set to 1b and a stop condition is detected, a status interrupt request signal (IICBTIS) is generated.

37.7.1.2 Continuous Transfer Mode

(1) Data Transmission/Reception Interrupt Request Signal (IICBTIA)

The following shows the conditions under which the IICBTIA signal is generated in continuous transfer mode.

- Conditions for generating an interrupt request signal upon reception

When the receive data is stored from the shift register to the IICB0DAT register (**Figure 37.7-1**, timing (1))

Figure 37.7-1 IICBTIA Signal Generation Timing (Reception, Continuous Transfer Mode)

- Conditions for generating an interrupt request signal during transmission

When no transmit data is in the shift register and IICB0DAT register, data is written to the IICB0DAT register (**Figure 37.7-2**, timing (2))

When data is stored from the IICB0DAT register to the shift register (**Figure 37.7-2**, timing (1))

Figure 37.7-2 IICBTIA Signal Generation Timing (Transmission, Continuous Transfer Mode)

(2) Status Interrupt Request Signal (IICBTIS)

The IICBTIS signal generation timing in the continuous transfer mode is the same as that in the single transfer mode.

Table 37.7-4 IICBTIS Signal Generation Timing

| Generation Timing | Description                                                                                                  | Reference                                                                            |

| 0b            | 1b            | x             | Reception             | 1b            | 1b            | IICBTIS when IICB0DAT is read   | Wait |

**Note:** x: Don't care

**Note:** In the case of  $\Delta 1$ , the value of IICB0STR0.IICB0SSAC bit is always 0b.

Note 1. The operation when restarting without reading after reception is completed

Note 2. The addresses matched before the restart condition

**(b) IICBTIS Signal Generation Conditions during Data Transfer**

$\Delta 2$  and  $\Delta 3$  in **Table 37.7-4** are the IICBTIS signal generation timing during data transfer. **Table 37.7-6** lists the conditions for IICBTIS signal generation at the  $\Delta 2$  and  $\Delta 3$  timing.

Table 37.7-6 IICBTIS Signal Generation Condition during Data Transfer (Continuous Transfer Mode)

| 0b            | 1b            | 0b            | x             | Reception             | 1b            | 0b            | *1                         | —          | —    | IICBTIS<br>after<br>IICB0DAT<br>is read | Wait |

**Note:** x: Don't care

Note 1. IICB0TRG.IICB0STT bit = 1b or 1b is not written to IICB0TRG.IICB0SPT bit

Note 2. IICB0TRG.IICB0STT bit = 1b or 1b is written to IICB0TRG.IICB0SPT bit

**(c) IICBTIS Signal Generation when Stop Condition is Detected**

$\Delta 4$  in **Table 37.7-4** is the IICBTIS signal generation timing when a stop condition is detected.

The IICB0CTL0.IICB0SLSI bit setting controls the generation of the IICBTIS signal; when the IICB0CTL0.IICB0SLSI bit is set to 1, the IICBTIS signal is generated when a stop condition is detected.

### 37.7.2 Interrupt Output and Status

This section describes the states of the IICBnSTR0 register at the time of interrupt output generation by communications flow. The meanings of the symbols which are used in the figures are as follows.

|                                         |                                  |
|-----------------------------------------|----------------------------------|
| ST:                                     | Start condition                  |
| AD6-AD0:                                | Address                          |
| R, $\overline{W}$ , R/ $\overline{W}$ : | Transfer direction specification |
| $\overline{ACK}$ :                      | Acknowledge                      |
| NACK:                                   | Non-acknowledge                  |
| D7-D0:                                  | Data                             |
| SP:                                     | Stop condition                   |

### 37.7.2.1 Single Transfer Mode (Master Operation)

37.7.2.4 Single Transfer Mode (Operation in the Case of Non-Participation in Communications)

(1) Start - Code - Data - Data - Stop

### 37.7.2.5 Single Transfer Mode (Operation in the Case of Arbitration Loss: Operation as a Slave after Arbitration Loss)

When using the IIC as a master in the multi-master system, read the IICB0STR0.IICB0ALDF bit each time an IICBTIS interrupt is generated to check the result of arbitration.

#### (1) In the Case of Address Match after a Loss in Arbitration

##### (a) When the IICB0CTL0.IICB0SLWT bit = 0b

##### (b) When the IICB0CTL0.IICB0SLWT bit = 1b

**(2) When the Extension Code is Detected after a Loss in Arbitration****(a) When the IICB0CTL0.IICB0SLWT bit = 0b****(b) When the IICB0CTL0.IICB0SLWT bit = 1b**

37.7.2.6 Single Transfer Mode (Operation in the Case of Arbitration Loss: Non-Participation in Communications after Arbitration Loss)

When using the IIC as a master in the multi-master system, read the IICB0STR0.IICB0ALDF bit each time an IICBTIS interrupt is generated to check the result of arbitration.

(1) In the Case of a Loss in Arbitration during Transmission of Slave Address Data

(2) In the Case of a Loss in Arbitration during Data Transfer

(a) When the IICB0CTL0.IICB0SLWT bit = 0b

(b) When the IICB0CTL0.IICB0SLWT bit = 1b

**(3) In the Case of a Loss in Arbitration for the Restart Condition during Data Transfer****(a) When the IICB0CTL0.IICB0SLWT bit = 1 (Extension Code Mismatch, Address Mismatch)****(4) In the Case of a Loss in Arbitration for the Stop Condition during Data Transfer**

**(5) In the Case of a Loss in Arbitration when the SDAm Pin is at the Low Level at the Time of the Attempt to Generate the Restart Condition**

**(a) When the IICB0CTL0.IICB0SLWT bit = 0b**

**(b) When the IICB0CTL0.IICB0SLWT bit = 1b**

### 37.7.2.13 Continuous Transfer Mode (in Slave Operation (Transmission): Extension Code Reception)

#### CAUTION

The interrupts enclosed in brackets [ ] indicate the states at the time of interrupts which do not place the IIC in the wait state. These interrupts are not generated at the time of interrupts in response to the detection of the stop condition.

Figure 37.8-8 Procedure for Setting the Continuous Transfer Mode when the Communication Reservation Function is Disabled (Multi-Master Environment) (2/2)

## 37.9 Usage Notes

### 37.9.1 Restrictions on the Change Timing of the SCL/SDA Line

This unit determines the status by sampling the respective lines of SCL and SDA with the APB clock (PCLK). Therefore, when SCL and SDA change at the timing shown in **Figure 37.9-1**, this is not judged as a start condition (restart condition).

The IIC bus specification does not define the operation when such a timing change occurs.

Figure 37.9-1 Timing Example for Determining Simultaneous Change

### 37.9.2 Restrictions on the Start Condition Hold Time

This unit may set the SCL line to a low level at the timing that does not satisfy the start condition hold time ( $t_{HD:STA}$ ).

When this unit is operating as the master, after the  $T_{su:sta}$  time has elapsed, if the SDA line changes by the external source and the set low-width time elapses before this unit detects the change, the SCL line is set to a low level at the time less than  $t_{HD:STA}$ . In this case, the unit will not lose in arbitration and continue to operate as the master.

Figure 37.9-2 Timing Example where Start Condition Hold Time is Not Satisfied

## Section 38 Clocked Serial Interface (CSI)

This section describes the functions of the clocked serial interface (CSI).

### 38.1 Functional Overview

The CSI is an interface for clock synchronized serial communication that uses three signals: the serial clock (SCK), serial data input (SI), and serial data output (SO); and it is compatible with the SPI (Serial Peripheral Interface).

The CSI can handle the slave selection (SS) signal as an input and in this case can operate as an SPI slave. It can also handle the slave selection (SS) signal as an output and in this case can operate as an SPI master.

This LSI has a total of six CSIs from ch. 0 to ch. 5. Of those, ch. 1, ch. 2, ch. 3, and ch. 5 are for use with the ISP support package, so do not use registers related to those channels.

In addition, since the DMAC is for use with the ISP support package, do not use the DMA transfer method for the CSI.

#### 38.1.1 Features

- Master reception-only mode, master transmission/reception mode, slave reception-only mode, or slave transmission/reception mode is selectable.
- The serial data length is selectable from 8 or 16 bits.
- The first bit of serial data is selectable from MSB or LSB.
- The serial clock is selectable as the master clock divided by values from 2 to 32766 (the master clock frequency is up to 48 MHz).
- The serial clock input frequency is up to 24 MHz in slave mode.
- Data transfer in response to interrupts or DMA transfer by the external DMA controller is selectable.
- Two 16-bit (8-bit + 8-bit) 16-stage FIFO buffers are included, one for transmission and one for reception.
- The waiting time between serial data is specifiable in master mode.

### 38.1.2 Block Diagram

The figure below is a block diagram of the CSI.

Figure 38.1-1 Block Diagram

38.1.3 Connection Configuration

Figure 38.1-2 shows the CSI connection configuration.

Figure 38.1-2 Connection Configuration

## 38.2 Pin Functions

### 38.2.1 List of Internal Pins

Table 38.2-1 lists the internal pins of the CSI.

Table 38.2-1 List of Internal Pins

| Pin Name            | I/O       | Function                                                                                                                           |

**Note:** m = 0 to 5, x: Don't care

### 38.3.2 Register Descriptions

The function description of each register is given below.

The prefix (CSIm\_) of the register names is omitted in the register descriptions and the field descriptions in this section.

#### 38.3.2.1 CSI Mode Control Register (CSIm\_CSI\_MODE) (m = 0 to 5)

This register controls the serial communication processing of CSI. It is initialized to 0b by a reset. This register is set before communication starts for basic communication settings such as CSI communication mode, data length, and head data selection. It also monitors the communication status and starts and stops communication.

DATWT, TRMD, CCL, and DIR may not be changed during the communication (CSIE=1b or CSOT=1b). Therefore, when setting these bits, set the CSIE bit to 0b and read the CSOT bit to confirm that communication has stopped.

The CSIE bit should not be changed with other bits simultaneously.

**Access Size:** 32 bits

**Address:** <CSIO\_S0\_base> + 0000h  
<CSI1\_S0\_base> + 0000h  
<CSI2\_S0\_base> + 0000h  
<CSI3\_S0\_base> + 0000h  
<CSI4\_S0\_base> + 0000h  
<CSI5\_S0\_base> + 0000h

**Initial Value:** 0000\_0000h

Table 38.3-2 CSIm\_CSI\_MODE Register Contents (2/2)

| Bit Position | Bit Name | Description                                                                                                             |
|--------------|----------|-------------------------------------------------------------------------------------------------------------------------|
| 4            | DIR      | Select the first data of serial data.<br>0b: MSB (initial value)<br>1b: LSB                                             |
| 3 to 1       | —        | Reserved. These bits are read as 0b. The write value should always be 0b.                                               |
| 0            | CSOT     | The communication state flag. Writing is invalid.<br>0b: Communication is stopped.<br>1b: Communication is in progress. |

### 38.3.2.2 CSI Clock Select Register (CSIm\_CSI\_CLKSEL) (m = 0 to 5)

This register selects master/slave mode, sets the slave selection pin (SS pin), selects the clock polarity and data phase for serial communication, and selects the baud rate. Initialize the SLAVE bit to 1b and other bits to 0b by a reset.

This register may not be rewritten. Therefore, when setting, set the CSIE bit to 0 and read the CSOT bit to confirm that communication has stopped.

Also, issue a CSI reset after changing the setting.

**Access Size:** 32 bits

**Address:** <CSI0\_S0\_base> + 0004h  
<CSI1\_S0\_base> + 0004h  
<CSI2\_S0\_base> + 0004h  
<CSI3\_S0\_base> + 0004h  
<CSI4\_S0\_base> + 0004h  
<CSI5\_S0\_base> + 0004h

**Initial Value:** 0000\_FFEh

The write value should always be 0b.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |           |       |       |                  |       |     |       |     |       |     |       |     |       |      |       |      |       |       |       |        |       |                         |

### 38.3.2.3 CSI Control Register (CSIm\_CSI\_CNT) (m = 0 to 5)

This register controls and sets CSI. This register consists of software reset, trigger function enable/disable, transmit and receive status display, DMA mode enable/disable, interrupt mask, and SS pin level monitor bits for CSI. Resetting initializes the CSIRST bit to 1b and all other bits to 0b. However, the initial value of the SS\_MON bit depends on the SS pin. During communication (CSIE = 1b or CSOT = 1b), a value different from the previous value may not be written except for the interrupt control bits (bits[13: 0]). If these bits are rewritten during communication, operation is not guaranteed.

**Access Size:** 32 bits

**Address:** <CSI0\_S0\_base> + 0008h  
 <CSI1\_S0\_base> + 0008h  
 <CSI2\_S0\_base> + 0008h  
 <CSI3\_S0\_base> + 0008h  
 <CSI4\_S0\_base> + 0008h  
 <CSI5\_S0\_base> + 0008h

**Initial Value:** 10x0\_0000h

### 38.3.2.4 CSI Interrupt Status Register (CSIm\_CSI\_INT) (m = 0 to 5)

This register is used to read and clear the interrupt factors. It is initialized to 0b by a reset.

In addition, when clearing the interrupt factor, release the interrupt cause before clearing it. Even if interrupts are disabled in the CSI\_CNT register, each bit is asserted if the condition is met.

**Access Size:** 32 bits

**Address:** <CSI0\_S0\_base> + 000Ch  
 <CSI1\_S0\_base> + 000Ch  
 <CSI2\_S0\_base> + 000Ch  
 <CSI3\_S0\_base> + 000Ch  
 <CSI4\_S0\_base> + 000Ch  
 <CSI5\_S0\_base> + 000Ch

**Initial Value:** 0000\_0000h

### 38.3.2.5 CSI Receive FIFO Level Indicate Register (CSIm\_CSI\_IFIFOL) (m = 0 to 5)

CSI is equipped with a 16-stage receive FIFO buffer (1 stage is 8 bits + 8 bits) to store the received data.

This register indicates the receive FIFO buffer usage in bytes (8 bits). It is initialized by a reset or CSI reset (CIRST=1b in CSI\_MODE register).

When the serial data length is 8 bits (CCL = 0b in the CSI\_MODE register), it is incremented by 1 each time data is received in the receive FIFO buffer and is decremented by 1 each time data (8 bits) is read from the receive FIFO buffer.

When the serial data length is 16 bits (CCL = 1b in CSI\_MODE register), it is incremented by 2 each time data is received in the receive FIFO buffer and is decremented by 2 each time data (16 bits) is read from the receive FIFO buffer.

Writing to this register deletes the whole receive FIFO buffer (flush) regardless of the written value and sets RFL[5:0]=000000b.

Writing is prohibited during communication (when CSIE in the CSI\_MODE register is 1 or CSOT = 1b).

**Access Size:** 32 bits

**Address:** <CSI0\_S0\_base> + 0010h  
<CSI1\_S0\_base> + 0010h

### 38.3.2.6 CSI Transmit FIFO Level Indicate Register (CSIm\_CSI\_OFIFOL) (m = 0 to 5)

CSI is equipped with a 16-stage transmit FIFO buffer (1 stage is 8 bits + 8 bits) to store the transmit data.

This register indicates the transmit FIFO buffer usage in bytes (8 bits). It is initialized by a reset or CSI reset (CIRST=1b in CSI\_MODE register).

When the serial data length is 8 bits (CCL = 0b in CSI\_MODE register), it is incremented by 1 each time data is written in the transmit FIFO buffer and is decremented by 1 each time data (8 bits) is transmitted from the transmit FIFO buffer.

When the serial data length is 16 bits (CCL = 1b in CSI\_MODE register), it is incremented by 2 each time data is written in the transmit FIFO buffer and is decremented by 2 each time data (16 bits) is transmitted from the transmit FIFO buffer.

Writing to this register deletes the whole transmit FIFO buffer (flush) regardless of the written value and sets TFL[5:0]=000000b.

Writing is prohibited during communication (when CSIE in the CSI\_MODE register is 1 or CSOT = 1b).

**Access Size:** 32 bits

**Address:** <CSI0\_S0\_base> + 0014h  
<CSI1\_S0\_base> + 0014h

|--------------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 6      | —        | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                                                            |
| 5 to 0       | TFL      | <p>The number of bytes occupied in the transmit FIFO buffer.</p> <p>Read:</p> <p>000000b: The transmit FIFO buffer is empty.<br/> 000001b: 1 byte<br/> 000010b: 2 bytes<br/>  <br/> 011111b: 31 bytes<br/> 100000b: 32 bytes<br/> 100001b to 111111b: Reserved.</p> <p>Write:</p> <p>Regardless of the written value, delete the transmit FIFO buffer data and set the register value to 0b simultaneously.</p> |

38.3.2.7 CSI Receive Window Register (CSIm\_CSI\_IFIFO) (m = 0 to 5)

This register is a window register used to read data in the receive FIFO buffer. Every time this register is read, the read pointer is moved to read the latest data input to the receive FIFO buffer. The contents of this register are valid when the receive FIFO Level Indicate Register (CSI\_IFIFO) is not 0. When the serial data length is 8 bits (CCL=0b in the CSI\_MOE register) use the lower 8 bits. When the serial data length is 16 bits (CCL=1b in the CSI\_MOE register) use the lower 16 bits.

Table 38.3-8 CSIm\_CSI\_IFIFO Register Contents

| Bit Position | Bit Name    | Description                                                               |
|--------------|-------------|---------------------------------------------------------------------------|
| 31 to 16     | —           | Reserved. These bits are read as 0b. The write value should always be 0b. |
| 15 to 0      | IFIFO[15:0] | Rx FIFO register data. Writing is invalid.                                |

38.3.2.8 CSI Transmit Window Register (CSIm\_CSI\_OFIFO) (m = 0 to 5)

This register is a window register used to write data to the transmit FIFO buffer. Every time data is written to this register, the write pointer is moved and the transmit data is stored. If DMA transfer is not used, read the CSI transmit window register (CSI\_OFIFOL register) to confirm that the transmit FIFO buffer is not full before writing. When the serial data length is 8 bits (CCL=0b in the CSI\_MOE register) use the lower 8 bits. When the serial data length is 16 bits (CCL=1b in the CSI\_MOE register) use the lower 16 bits.

Table 38.3-9 CSIm\_CSI\_OFIFO Register Contents

| Bit Position | Bit Name    | Description                                                               |
|--------------|-------------|---------------------------------------------------------------------------|
| 31 to 16     | —           | Reserved. These bits are read as 0b. The write value should always be 0b. |
| 15 to 0      | OFIFO[15:0] | Tx FIFO register data. These bits are read as 0b.                         |

### 38.3.2.9 CSI FIFO Trigger Level Register (CSIm\_CSI\_FIFOTRG) (m = 0 to 5)

This register sets the trigger level of the transmit FIFO buffer and the receive FIFO buffer. If the receive FIFO trigger level setting is valid (R\_TRGEN=1b in the CSI\_CNT register), the R\_TRG[2:0] bit setting is valid. And if the transmit FIFO trigger level setting is valid (T\_TRGEN=1 in the CSI\_CNT register), the T\_TRG[2:0] bit setting is valid.

**Access Size:** 32 bits

**Address:** <CSI0\_S0\_base> + 0020h  
 <CSI1\_S0\_base> + 0020h  
 <CSI2\_S0\_base> + 0020h  
 <CSI3\_S0\_base> + 0020h  
 <CSI4\_S0\_base> + 0020h  
 <CSI5\_S0\_base> + 0020h

**Initial Value:** 0000\_0000h

|                |            | 8 bits      16 bits                                                                                                                                                                             |
| 000b           |            | 8 bits × 1      16 bits × 1                                                                                                                                                                     |
| 001b           |            | 8 bits × 2      16 bits × 2                                                                                                                                                                     |
| 010b           |            | 8 bits × 4      16 bits × 4                                                                                                                                                                     |
| 011b           |            | 8 bits × 8      16 bits × 8                                                                                                                                                                     |
| 100b           |            | 8 bits × 16      16 bits × 16                                                                                                                                                                   |
| 101b           |            | 8 bits × 32      Prohibited*1                                                                                                                                                                   |
| 110b           |            | Prohibited*1      Prohibited*1                                                                                                                                                                  |
| 111b           |            | Prohibited*1      Prohibited*1                                                                                                                                                                  |

Note 1. Do not set the corresponding value. Operation is not guaranteed if the setting is made.

## 38.4 Operation

The prefix (CSIm\_) of the register names is omitted in this and subsequent sections.

### 38.4.1 Software Reset

This unit has a software reset (CSI reset) function by a register setting, in addition to a reset by the PRESETn signal.

While a reset by the PRESETn signal initializes all registers, a CSI reset clears the interrupt flag and the transmission and reception FIFO buffers. It also initializes the specified registers.

#### 38.4.1.1 CSI Reset Function

A CSI reset occurs when the CSI software reset (CSIRST) bit of the CSI control register (CSI\_CNT) is set. Clearing the CSIRST bit de-asserts the CSI reset.

The table below lists the pins and registers to be initialized by a CSI reset.

Table 38.4-1 Pins and Registers to be Initialized by a CSI Reset

| Category    | Pin Name or Register Name            | Bit Name                                    |
|-------------|--------------------------------------|---------------------------------------------|
| Pins*1      | SCKOE                                |                                             |
|             | SCKO                                 |                                             |
|             | SOOE (*Fixed to 0 in reception mode) |                                             |
| Registers*2 | CSI_MODE                             | CSIE, CSOT                                  |
|             | CSI_CNT                              | T_FIFOF, R_FIFOF                            |
|             | CSI_INT                              | UNDER, OVERF, TREND, CSIEND, T_TRGR, R_TRGR |
|             | CSI_IFIFOL                           | RFL[5:0]                                    |
|             | CSI_OFIFOL                           | TFL[5:0]                                    |

Note 1. The SCKOE pin is at the low level during a CSI reset regardless of the operating mode setting. When the CSI reset is de-asserted, the output on this pin goes to the level that is dependent on the operating mode.

Note 2. Writing to the above registers has no effect during a CSI reset (i.e., while CSIRST is 1b).  
When writing to these registers, only do so after the CSI reset has been de-asserted (i.e., CSIRST is set to 0b).

The registers other than those listed in **Table 38.4-1** are not initialized by a CSI reset but retain their values.

Since these registers retain the initial settings required for communications, operation can be restarted without re-setting them after the CSI reset has been de-asserted.

#### 38.4.1.2 Notes on Using a CSI Reset

Applying a CSI reset while operations for communications are in progress may disrupt communications in a way that affects operations by the other party.

To apply a CSI reset, clear the CSIE flag in the CSI mode control register (CSI\_MODE) and check that communications have been stopped (the CSOT flag is 0b) by reading the CSI mode control register (CSI\_MODE).

Similarly, applying a CSI reset during transmission or reception with the aid of DMA transfer may place the CSI in an unexpected state. When applying a CSI reset while DMA transfer is in use, only do so after having confirmed that DMA transfer has stopped.

### 38.4.2 Starting and Stopping Communications

Communications are started and stopped by using the CSIE flag of the CSI mode control register (CSI\_MODE).

Operations for communications are started when the flag is set and stopped when the flag is cleared.

The state of communications can be checked by reading the CSOT flag of the CSI mode control register (CSI\_MODE).

If the CSIE is cleared during the cycle of communications, operations for communications are not stopped immediately but are stopped after a wait for the completion of this cycle. Accordingly, poll the CSOT flag to check that communications have been stopped before proceeding with processing after stopping communications.

Only the registers and register bits listed below are writable while operations for communications are in progress.

Table 38.4-2 List of the Registers and Flags which are Writable during Operations for Communications

| Register Name | Flag                              |
|---------------|-----------------------------------|
| CSI_MODE      | CSIE                              |
| CSI_CNT       | Interrupt enable flag (bits 0:13) |
| CSI_INT       | All                               |
| CSI_OFIFO     | All                               |

#### 38.4.2.1 Notes on Using the CSIE Flag

Changing the settings of the registers other than those listed in **Table 38.4-2**, and which set the operating mode, communications data format, communications speed, or trigger level, is prohibited during operations for communications.

When changing the settings after starting communications, only do so after stopping communications.

The initial settings must be made before starting communications after the CSI reset has been de-asserted. Specifically, the initial settings for both master and slave must be completed before starting communications.

### 38.4.3 Setting the Communications Function

#### 38.4.3.1 Format of Serial Data

This unit can comply with four serial data formats by settings.

The CCL and DIR flags of the CSI mode control register (CSI\_MODE) are used to make the settings.

Set the following items such that the conditions for the master are the same as those for the slave.

- Serial data length (CCL):  
Select 8 or 16 bits as the serial data length.
- First bit of serial data (DIR):  
Select MSB or LSB for the first bit of serial data.

### 38.4.3.2 Serial Clock Timing

This unit can comply with four serial clock timings by settings.

The CKP and DAP flags of the CSI clock select register (CSI\_CLKSEL) are used to make the settings.

Set the following items such that the conditions for the master are the same as those for the slave.

- Polarity of the serial clock in the idle state (CKP):  
Select the polarity of the serial clock in the idle state as the high or low level.
- Phase of serial data (DAP):  
For SO, select the same phase as that of SCK or the phase half a cycle before that of SCK.

**Table 38.4-3** shows the timing of operations by the combination of the values of the polarity selection bit (CKP) while the serial clock is idle and the phase selection bit for serial data (DAP).

Table 38.4-3 Polarity of the Clock and the Phase of Data

| CKP Bit | DAP Bit | Operation Timing |
|---------|---------|------------------|
| 0       | 0       |                  |
| 0       | 1       |                  |
| 1       | 0       |                  |
| 1       | 1       |                  |

**Note:** The setting of the polarity selection bit (CKP) for the serial clock must match the clamp level of the SCK signal line.

- SCK is clamped at the high level: CKP ← 0b
- SCK is clamped at the low level: CKP ← 1b

38.4.3.3 Interval Time between Serial Data Communications

The serial clock and serial data are seamlessly transferred during continuous data transfer.

If the communications speed is too high, processing may not proceed in time. This depends on the connected slave. For communications with such slaves, an interval can be provided between the units of serial data.

An interval time is set by using the DATWT[3:0] bits of the CSI mode control register (CSI\_MODE).

Specifically, an interval equivalent to 0 to 15 clock cycles of the serial clock (SCKO) can be inserted through the setting of DATWT[3:0].

The figure below shows the timing when DATWT[3:0] = 0 and DATWT[3:0] = 4.

Figure 38.4-1 Interval Time Timing (when DATWT[3:0] = 0000b)

Master transmission/reception mode

Data length: 8 bits  
Direction of transfer: MSB  
Polarity of the clock: High level  
Data phase: Sampling after half a cycle

An interval time equivalent to four SCK clock cycles is inserted between transfers when DATWT[3:0] in CSI\_MODE = 0100b.

Figure 38.4-2 Interval Time Timing (when DATWT[3:0] = 0100b)

### 38.4.3.4 Slave Selection Signal Function and Setting

The slave selection signal can be used for operation in slave reception-only mode and slave transmission/reception mode.

This signal is used to select a slave for communications with the master in the system in which multiple slaves are connected to one master.

Figure 38.4-3 Example of Connections between the Master and Three Slaves

As shown in **Figure 38.4-3**, the master generates the slave selection signal by using a general-purpose port (GPIO), etc.

The master activates the slave selection signal of the other party before starting operations for communications and deactivates the slave selection signal before switching to communications with another slave.

The slave handles operations for communications based on the received serial clock signal while the slave selection signal is active.

The slave selection signal is set by using the SS\_ENA and SS\_POL flags of the CSI clock select register (CSI\_CLKSEL).

The table below gives the functional operations corresponding to the settings of these flags.

Table 38.4-4 Functional Operations of the Slave Selection Pin

| SS_ENA | SS_POL | Operation                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0b     | X      | <ul style="list-style-type: none"><li>• This setting is for one-to-one use of the master and slave.</li><li>• The slave's communications function is always active regardless of the signal level of the SS pin.</li><li>• Transmission/reception or reception starts in response to input of the serial clock (SCKI).</li><li>• In transmission/reception mode, the SOOE pin is always active.*1</li></ul> |
| 1b     | 0b     | <ul style="list-style-type: none"><li>• When the SS pin is at the low level, the slave's communications function is active.</li><li>• Operation corresponds to the serial clock (SCKI) while the SS pin is at the low level. In transmission/reception mode, the SOOE pin is active*1 while the SS pin is at the low level.</li></ul>                                                                       |
| 1b     | 1b     | <ul style="list-style-type: none"><li>• The slave's communications function is active when the SS pin is at the high level.</li><li>• Operation corresponds to the serial clock (SCKI) while the SS pin is at the high level. In transmission/reception mode, the SOOE pin is active*1 while the SS pin is at the high level.</li></ul>                                                                     |

Note 1. This pin is not active if the operations for communications are stopped (CSIE = 0b).

The slave handles operations for communications with the serial clock from the master. Accordingly, the slave selection signal must retain the active level while operations for communications are in progress.

Care should be taken with the following timing when the slave selection signal is generated.

The timing differs with the setting for the phase of serial data (DAP).

Figure 38.4-4 Slave Selection Signal Control Timing (when DAP = 0 for Slave)

Figure 38.4-5 Slave Selection Signal Control Timing (when DAP = 1b for Slave)

### 38.4.4 Interrupt

The CSI interrupt signal (CSIINT) is provided as an interrupt output signal.

CSIINT is a level interrupt.

Clearing the interrupt source flag in the CSI interrupt status register (CSI\_INT) deactivates the interrupt signal.

There are six interrupt sources listed below. The interrupt sources can be masked individually.

Table 38.4-5 List of Interrupt Sources

| Interrupt Source                     | Flag Name | Function                                                                                                                                                                                                                         |
|--------------------------------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Underrun error interrupt             | UNDER     | This interrupt occurs when the request for transmission is received while data for transmission have not been prepared in the transmission FIFO, i.e. it is empty.<br>For details, see <b>Section 38.4.5.2, Underrun Error</b> . |
| Overflow error interrupt             | OVERF     | This interrupt occurs when reception proceeds while the reception FIFO has no space.<br>For details, see <b>Section 38.4.5.1, Overflow Error</b> .                                                                               |
| All transmission completed interrupt | TREND     | An all transmission completed interrupt occurs when all data for transmission in the transmission FIFO have been transmitted.<br>This interrupt does not occur in master reception-only mode and slave reception-only mode.      |
| Transfer completed interrupt         | CSIEND    | A transfer completed interrupt occurs when reception or transmission/reception of a single unit of data is completed.<br>Operations for communications continue even if the transfer completed interrupt occurs.                 |
| Tx trigger level interrupt           | T_TRGR    | This interrupt occurs when the free space of the transmission FIFO reaches the specified trigger level due to the operation for transmission.<br>For details, see <b>Section 38.4.11.1, Transmission Trigger Level</b> .         |
| Rx trigger level interrupt           | R_TRGR    | This interrupt occurs if the buffering level of the reception FIFO reaches the specified trigger level due to the operation for reception.<br>For details, see <b>Section 38.4.11.2, Reception Trigger Level</b> .               |

### 38.4.4.1 All Transmission Completed Interrupt

An all transmission completed interrupt (TREND) occurs when all data for transmission in the transmission FIFO have been transmitted.

Figure 38.4-6 CSI All Transmission Completed Interrupt

However, as shown in **Figure 38.4-7**, even if an all transmission completed interrupt occurs, writing to the transmission FIFO by the DMAC may proceed after that and data for transmission may remain in the transmission FIFO.

When transmission is to be completed by the handler for the all transmission completed interrupt, check whether data for transmission remain in the transmission FIFO.

Figure 38.4-7 CSI All Transmission Completed Interrupt

### 38.4.5 Operation and Procedure for Processing when an Error Occurs

The CSI detects two errors: an overflow error in reception and an underrun error in transmission.

#### 38.4.5.1 Overflow Error

An overflow error occurs when reception proceeds while the reception FIFO buffer has no space.

An overflow error may occur in master transmission/reception mode, in slave reception-only mode, or in slave transmission/reception mode.

In master reception-only mode, an overflow error does not occur because communications are stopped before the buffer overflows.

If an overflow error occurs, subsequent data for reception are not captured. Note, however, that transmission which is proceeding at the same time is not stopped in master transmission/reception mode or in slave transmission/reception mode.

Reception is restarted when data have been read from the reception FIFO buffer or the overflow interrupt source flag is cleared after flushing of the buffer to make space in it.

An overflow can be detected by the interrupt signal.

For recovery from communications errors due to overflows, create a protocol in software to be triggered by the interrupt.

#### 38.4.5.2 Underrun Error

An underrun error occurs when the request for transmission is received while data for transmission have not been prepared in the transmission FIFO, i.e. it is empty.

An underrun error may only occur in slave transmission/reception mode.

If an underrun error occurs, transmission as well as reception is stopped.

The master receives 0-valued data because the serial data output (SO) pin is at the low level while transmission is stopped.

Data for reception which are transmitted from the master following an error are not captured because reception is stopped.

To restart operation, a CSI reset (CSIRST in the CSI\_CNT register = 1b) is used. Follow the procedure below to restart operation.

1. Assert the CSI reset signal.
2. De-assert the CSI reset signal.
3. Write data for transmission to the transmission FIFO.
4. Start communications (CSIE in CSI\_MODE = 1b).

An underrun error can be detected by the interrupt signal.

For recovery from communications errors due to underrun errors, create a protocol in software to be triggered by the interrupt.

### 38.4.6 Operating Mode

This unit has four operating modes listed below.

The operating mode must be determined by a register setting at start-up.

- Master reception-only mode
- Master transmission/reception mode
- Slave reception-only mode (default at the time of a reset)
- Slave transmission/reception mode

The operating mode is set with a combination of two flags, the SLAVE flag of the CSI clock select register (CSI\_CLKSEL) and the TRMD flag of the CSI mode control register (CSI\_MODE).

The operating mode should be set before starting communications after release from the reset state. The setting cannot be changed during communications (while CSIE = 1 or CSOT = 1 in the CSI\_MODE register).

Table 38.4-6 List of Operation Modes

| CSI_CLKSEL<br>SLAVE (Bit 15) | CSI_MODE<br>TRMD (Bit 6) | Operating Mode                     | Functional Overview                                                                                                |
|------------------------------|--------------------------|------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| 0b                           | 0b                       | Master reception-only mode         | This mode is dedicated for reception to receive data from a slave.                                                 |
| 0b                           | 1b                       | Master transmission/reception mode | In this mode, transmission and reception to and from a slave proceed simultaneously.                               |
| 1b                           | 0b                       | Slave reception-only mode          | This mode is dedicated for reception to receive data transmitted from the master (default at the time of a reset). |
| 1b                           | 1b                       | Slave transmission/reception mode  | In this mode, transmission and reception of data to and from the master proceed simultaneously.                    |

### 38.4.7 Master Reception-only Mode

This mode is dedicated for reception to receive data from a slave.

The transmission function is not used.

The master outputs the serial clock (SCK) along with operation for reception and receives serial data which are transmitted from a slave.

**Figure 38.4-8** shows an example of one-to-one connection with a slave.

Figure 38.4-8 Example of Connection in Master Reception-only Mode

### 38.4.7.1 Setting Items in Master Reception-only Mode

The table below lists the registers to be set in master reception-only mode.

Table 38.4-7 List of the Registers to be Set in Master Reception-only Mode

| *1  | Register Name | Bit Name                                    | Bit   | Setting                                                                                                               |
|-----|---------------|---------------------------------------------|-------|-----------------------------------------------------------------------------------------------------------------------|
| [R] | CSI_MODE      | Communications mode: TRMD                   | 6     | 0b (reception only)                                                                                                   |
| [R] |               | Serial data length: CCL                     | 5     | Select 16 bits or 8 bits. The data length for the slave and that for the master must match.                           |
| [R] |               | First bit: DIR                              | 4     | Select MSB or LSB. The first bit settings for the slave and master must match.                                        |
| [R] |               | Interval time: DATWT                        | 19:16 | Set an appropriate value as required. See <b>Section 38.4.3.3, Interval Time between Serial Data Communications</b> . |
| [R] | CSI_CLKSEL    | Operating mode: SLAVE                       | 15    | 0b (master)                                                                                                           |
| [R] |               | Polarity of the clock: CKP                  | 17    | The setting must match the clamp level of the SCK signal line.                                                        |
| [R] |               | Data phase: DAP                             | 16    | Select the phase of serial data.<br>It must match the data phase selection by the master.                             |
| [R] |               | Communications clock selection: CKS         | 14:1  | Determines the communications frequency of SCK.                                                                       |
| [O] | CSI_CNT       | DMA transfer for reception: R_DMAEN         | 16    | Determines the method for transfer of received data.                                                                  |
| [O] |               | Reception FIFO trigger level: R_TRGEN       | 19    | Determines use of the reception FIFO trigger level.                                                                   |
| [O] |               | Transfer completed interrupt: CSIEND_E      | 8     | Determines use of the transfer completed interrupt.                                                                   |
| [O] |               | Reception trigger level interrupt: R_TRGR_E | 0     | Determines use of the reception trigger level interrupt.                                                              |
| [O] | CSI_FIFOTRG   | Reception FIFO trigger level: R_TRG         | 2:0   | Determines the level value when the reception FIFO trigger level is used.                                             |

Note 1. [R]: Required setting items.  
[O]: Optional. Set these items as required.

### 38.4.7.2 Operation in Master Reception-only Mode

#### (1) How to Start Operation

After the initial settings, setting the startup flag for communications (the CSIE bit in CSI\_MODE) starts reception

#### (2) How to End Operation

Clearing the startup flag for communications (the CSIE bit in CSI\_MODE) stops reception.

If the startup flag is cleared during the reception cycle, transmission or reception is stopped after the completion of the cycle.

#### (3) Operation during Communications

When the reception FIFO buffer has no space, output of the serial clock SCK is stopped and overall operation for reception is stopped.

Reception is restarted when data have been read from the reception FIFO and the FIFO has space.

#### (4) Reception Trigger Level Interrupt

A reception trigger level interrupt can be used. For details of the reception trigger level, see **Section 38.4.11.2, Reception Trigger Level**.

If received data are accumulated to the value set in R\_TRG[2:0] of the CSI FIFO trigger level register (CSI\_FIFOTRG), a reception trigger level interrupt occurs and reception is stopped.

Reception is restarted when the reception trigger level interrupt source flag (R\_TRGR) in the CSI\_INT register is cleared by reading the data from the reception FIFO.

#### (5) Communications Error

No error occurs in master reception-only mode.

### 38.4.7.3 Settings in Master Reception-only Mode and Flow of Operations

The figure below shows a flow of operations for reception with the use of the reception trigger level interrupt in master reception-only mode.

Figure 38.4-9 Flow of Operations with Interrupt Transfer in Master Reception-only Mode (1/3)

Figure 38.4-9 Flow of Operations with Interrupt Transfer in Master Reception-only Mode (2/3)

Figure 38.4-9 Flow of Operations with Interrupt Transfer in Master Reception-only Mode (3/3)

### 38.4.8 Master Transmission/Reception Mode

In this mode, transfer to and from a slave proceeds.

It allows high-speed communications since transmission and reception proceed simultaneously.

The master outputs the serial clock (SCK) during transfer.

Operation must be in this mode even when the transmission function is only used and the reception function is not used.

**Figure 38.4-10** shows an example of connection with multiple slaves.

Figure 38.4-10 Example of Connection in Master Transmission/Reception Mode (Connection with Multiple Slaves)

### 38.4.8.1 Setting Items in Master Transmission/Reception Mode

The table below lists the registers to be set in master transmission/reception mode.

Table 38.4-8 List of the Registers to be Set in Master Transmission/Reception Mode

| *1  | Register Name | Bit Name                                       | Bit   | Setting                                                                                                               |
|-----|---------------|------------------------------------------------|-------|-----------------------------------------------------------------------------------------------------------------------|
| [R] | CSI_MODE      | Communications mode: TRMD                      | 6     | 1b (transmission/reception mode)                                                                                      |
| [R] |               | Serial data length: CCL                        | 5     | Select 16 bits or 8 bits. The data length for the slave and that for the master must match.                           |
| [R] |               | First bit: DIR                                 | 4     | Select MSB or LSB. The first bit settings for the slave and master must match.                                        |
| [R] |               | Interval time: DATWT                           | 19:16 | Set an appropriate value as required. See <b>Section 38.4.3.3, Interval Time between Serial Data Communications..</b> |
| [R] | CSI_CLKSEL    | Operating mode: SLAVE                          | 15    | 0b (master)                                                                                                           |
| [R] |               | Polarity of the clock: CKP                     | 17    | The setting must match the clamp level of the SCK signal line.                                                        |
| [R] |               | Data phase: DAP                                | 16    | Select the phase of serial data.<br>It must match the data phase selection by the master.                             |
| [R] |               | Communications clock selection: CKS            | 14:1  | Determines the communications frequency of SCK.                                                                       |
| [O] | CSI_CNT       | DMA transfer for transmission: T_DMAEN         | 24    | Determines the method for transfer of data for transmission.                                                          |
| [O] |               | Transmission FIFO trigger level: T_TRGEN       | 27    | Determines use of the transmission FIFO trigger level.                                                                |
| [O] |               | DMA transfer for reception: R_DMAEN            | 16    | Determines the method for transfer or received data.                                                                  |
| [O] |               | Reception FIFO trigger level: R_TRGEN          | 19    | Determines use of the reception FIFO trigger level.                                                                   |
| [O] |               | All transmission completed interrupt: TREND_E  | 9     | Determines use of the all transmission completed interrupt.                                                           |
| [O] |               | Overflow interrupt: OVERF_E                    | 12    | Determines use of the overflow interrupt.                                                                             |
| [O] |               | Transfer completed interrupt: CSIEND_E         | 8     | Determines use of the transmission completed interrupt.                                                               |
| [O] |               | Transmission trigger level interrupt: T_TRGR_E | 4     | Determines use of the transmission trigger level interrupt.                                                           |
| [O] | CSI_FIFOTRG   | Reception trigger level interrupt: R_TRGR_E    | 0     | Determines use of the reception trigger level interrupt.                                                              |
| [O] |               | Transmission FIFO trigger level: T_TRG         | 10:8  | Sets the level value when the transmission FIFO trigger level is used.                                                |
| [O] |               | Reception FIFO trigger level: R_TRG            | 2:0   | Sets the level value when the reception FIFO trigger level is used.                                                   |

Note 1. [R]: Required setting items  
[O]: Optional. Set these items as required.

### 38.4.8.2 Operation in Master Transmission/Reception Mode

#### (1) How to Start Operation

After the initial settings, setting the startup flag for communications (the CSIE bit in CSI\_MODE) and writing data for transmission to the transmission FIFO starts operations for transmission and reception.

If data for transmission have been written to the transmission FIFO before setting the startup flag, only setting the startup flag starts operations for transmission and reception.

#### (2) How to End Operation

Clearing the startup flag for communications (the CSIE bit in CSI\_MODE) stops operations for transmission and reception.

Even if data for transmission remain in the transmission FIFO at the time the startup flag is cleared, operations for transmission and reception are stopped.

Clearing the startup flag after a wait until the communications state flag indicates stopping of communications can prevent data from remaining in the transmission FIFO.

#### (3) Operation during Communications

Operations for transmission and reception proceed until the transmission FIFO buffer has no data.

When the transmission FIFO buffer has no data for transmission and the buffer is empty, output of the serial clock SCK is stopped and operations for transmission and reception are stopped.

When transmission and reception are stopped, writing data to the transmission FIFO restarts operations for transmission and reception.

Since transmission is main operation in operations for transmission and reception, transmission and reception are not stopped even if the reception FIFO becomes full during operation. In such cases, an overflow error occurs and subsequent data for reception are not captured.

For details of an overflow error, see **Section 38.4.5.1, Overflow Error**.

#### (4) Reception Trigger Level Interrupt

A reception trigger level interrupt can be used. For details, see **Section 38.4.11.2, Reception Trigger Level**.

This interrupt occurs when received data are accumulated to the value set in R\_TRG of the CSI\_FIFOTRG register.

Operations for transmission and reception continue even if the reception trigger level interrupt has occurred.

**(5) Transmission Trigger Level Interrupt**

A transmission trigger level interrupt can be used. For details, see **Section 38.4.11.1 Transmission Trigger Level**.

The transmission trigger level interrupt occurs when data in the transmission FIFO are reduced due to the operation for transmission and the free space increases to the value set in T\_TRG.

Even if this interrupt occurs, operations for transmission and reception continue.

If the transmission trigger level interrupt is to be used, fill the transmission FIFO with data for transmission before starting communications in order to generate the first interrupt.

**(6) Communications Error**

An overflow error may occur.

### **38.4.8.3 Settings in Master Transmission/Reception Mode and Flow of Operations (for Transmission and Reception)**

The figure below shows a flow of operations for transmission and reception with the use of the transmission trigger level interrupt in master transmission/reception mode.

Data for transmission prepared in the transmission buffer are continuously transferred with the use of the transmission trigger level interrupt and the all transmission completed interrupt.

Figure 38.4-11 Flow of Operations with Interrupt Transfer in Master Transmission/Reception Mode (for Transmission and Reception) (1/4)

Figure 38.4-11 Flow of Operations with Interrupt Transfer in Master Transmission/Reception Mode (for Transmission and Reception) (2/4)

Figure 38.4-11 Flow of Operations with Interrupt Transfer in Master Transmission/Reception Mode (for Transmission and Reception) (3/4)

Figure 38.4-11 Flow of Operations with Interrupt Transfer in Master Transmission/Reception Mode (for Transmission and Reception) (4/4)

#### **38.4.8.4 Settings in Master Transmission/Reception Mode and Flow of Operations (for Transmission-only Operation)**

The figure below shows a flow of operations for transmission with the use of the transmission trigger level interrupt in master transmission/reception mode.

Data for transmission prepared in the transmission buffer are continuously transferred with the use of the transmission trigger level interrupt and the all transmission completed interrupt. Since the transmission function is only used, processing of received data is not handled.

Figure 38.4-12 Flow of Operations with Interrupt Transfer in Master Transmission/Reception Mode (for Transmission-only Operation) (1/3)

Figure 38.4-12 Flow of Operations with Interrupt Transfer in Master Transmission/Reception Mode (for Transmission-only Operation) (2/3)

Figure 38.4-12 Flow of Operations with Interrupt Transfer in Master Transmission/Reception Mode (for Transmission-only Operation) (3/3)

### 38.4.9 Slave Reception-Only Mode

This mode is dedicated for reception to receive data transmitted from the master.

The transmission function is not used.

The slave operates in response to the serial clock (SCK) from the master.

Due to the slave section (SS pin) mechanism, one slave can communicate with the master in the system connected to multiple slaves.

Slave reception-only mode is a default mode at the time of a reset.

**Figure 38.4-13** shows an example of connection with the master.

Figure 38.4-13 Example of Connections in Slave Reception-only Mode

### 38.4.9.1 Setting Items in Slave Reception-only Mode

The table below lists the registers to be set in slave reception-only mode.

Table 38.4-9 List of the Registers to be Set in Slave Reception-only Mode

| *1  | Register Name | Bit Name                                        | Bit | Setting                                                                                                                      |
|-----|---------------|-------------------------------------------------|-----|------------------------------------------------------------------------------------------------------------------------------|
| [R] | CSI_MODE      | Communications mode: TRMD                       | 6   | 0b (reception-only)                                                                                                          |
| [R] |               | Serial data length: CCL                         | 5   | Select 16 bits or 8 bits. The data length for the slave and that for the master must match.                                  |
| [R] |               | First bit: DIR                                  | 4   | Select MSB or LSB. The first bit settings for the slave and master must match.                                               |
| [R] | CSI_CLKSEL    | Operating mode: SLAVE                           | 15  | 1b (slave)                                                                                                                   |
| [O] |               | Control by the SS pin: SS_ENA                   | 19  | Determines use of the SS pin. Whether the SS pin is to be used depends on the system configuration.                          |
| [O] |               | Selection of the polarity of the SS pin: SS_POL | 18  | Selects the active level when the SS pin is used. It must match the active level of the control signal output by the master. |
| [R] |               | Polarity of the clock: CKP                      | 17  | The settings for the slave and master must match.                                                                            |
| [R] |               | Data phase: DAP                                 | 16  | Select the phase of serial data.<br>It must match the data phase selection by the master.                                    |
| [O] | CSI_CNT       | DMA transfer for reception: R_DMAEN             | 16  | Determines the method for transfer or received data.                                                                         |
| [O] |               | Reception FIFO trigger level: R_TRGEN           | 19  | Determines use of the reception FIFO trigger level.                                                                          |
| [O] |               | Overflow interrupt: OVERF_E                     | 12  | Determines use of the overflow interrupt.                                                                                    |
| [O] |               | Transfer completed interrupt: CSIEND_E          | 8   | Determines use of the transmission completed interrupt.                                                                      |
| [O] |               | Reception trigger level interrupt: R_TRGR_E     | 0   | Determines use of the reception trigger level interrupt.                                                                     |
| [O] | CSI_FIFOTRG   | Reception FIFO trigger level: R_TRG             | 2:0 | Sets the level value when the reception FIFO trigger level is used.                                                          |

### 38.4.9.2 Operation in Slave Reception-only Mode

#### (1) How to Start Operation

Reception starts following setting of the startup flag for communications (the CSIE bit in CSI\_MODE) and the input of the serial clock (SCKI) after the initial settings.

When the control function of the SS pin is set, reception starts when the SS pin is asserted and the serial clock (SCKI) is input after the startup flag for communications has been set. For the specifications of the SS pin, see **Section 38.5.2, Timing of Serial Communications (Continuous Data Transfer)**.

The slave starts to read serial data (SI) on reception of the serial clock (SCK).

Since operations for communications start in response to reception of the serial clock and serial data output by the master, the initial setting must be completed before the master starts communications.

#### (2) How to End Operation

Clearing the startup flag for communications (the CSIE bit in CSI\_MODE) stops reception.

If the startup flag is cleared during communications, reception is stopped after the completion of communications.

After reception is stopped, the slave does not respond to the request for reception from the master.

#### (3) Operation during Communications

When the slave receives the serial clock and serial data from the master, it writes the received data to the reception FIFO.

If the slave receives data while the reception FIFO has no space, an overflow error occurs and the subsequent data for reception are discarded.

To prevent data from being discarded, received data must be read to make space in the reception FIFO.

For details of an overflow error, see **Section 38.4.5.1, Overflow Error**.

#### (4) Reception Trigger Level Interrupt

A reception trigger level interrupt can be used. For details, see **Section 38.4.11.2, Reception Trigger Level**.

This interrupt occurs when received data are accumulated to the value set in R\_TRG of the CSI\_FIFOTRG register.

Reception will continue even if the reception trigger level interrupt occurs.

#### (5) Communications Error

An overflow error may occur.

### 38.4.9.3 Settings in Slave Reception-only Mode and Flow of Operations

The figure below shows a flow of operations for reception with the use of the reception trigger level interrupt in slave reception-only mode.

Figure 38.4-14 Flow of Operations with Interrupt Transfer in Slave Reception-only Mode (1/3)

Figure 38.4-14 Flow of Operations with Interrupt Transfer in Slave Reception-only Mode (2/3)

Figure 38.4-14 Flow of Operations with Interrupt Transfer in Slave Reception-only Mode (3/3)

### 38.4.10 Slave Transmission/Reception Mode

In this mode, transmission and reception of data to and from the master proceed simultaneously.

The slave operates in response to the serial clock (SCK) from the master.

It allows high-speed communications since transmission and reception proceed simultaneously.

Operation must be in this mode even when the transmission function is only used and the reception function is not used.

Due to the slave section (SS pin) mechanism, one slave can communicate with the master in the system connected to multiple slaves.

Figure 38.4-15 shows an example of connection with the master.

Figure 38.4-15 Example of Connection in Slave Transmission/Reception Mode

### 38.4.10.1 Setting Items in Slave Transmission/Reception Mode

The table below lists the registers to be set in slave transmission/reception mode.

Table 38.4-10 List of the Registers to be Set in Slave Transmission/Reception Mode

| *1  | Register Name | Bit Name                                        | Bit  | Setting                                                                                                                      |
|-----|---------------|-------------------------------------------------|------|------------------------------------------------------------------------------------------------------------------------------|
| [R] | CSI_MODE      | Communications mode: TRMD                       | 6    | 1b (transmission/reception mode)                                                                                             |
| [R] |               | Serial data length: CCL                         | 5    | Select 16 bits or 8 bits. The data length for the slave and that for the master must match.                                  |
| [R] |               | First bit: DIR                                  | 4    | Select MSB or LSB. The first bit settings for the slave and master must match.                                               |
| [R] | CSI_CLKSEL    | Operating mode: SLAVE                           | 15   | 1b (slave)                                                                                                                   |
| [O] |               | Control by the SS pin: SS_ENA                   | 19   | Determines use of the SS pin. Whether the SS pin is to be used depends on the system configuration.                          |
| [O] |               | Selection of the polarity of the SS pin: SS_POL | 18   | Selects the active level when the SS pin is used. It must match the active level of the control signal output by the master. |
| [R] |               | Polarity of the clock: CKP                      | 17   | The settings for the slave and master must match.                                                                            |
| [R] |               | Clock phase: DAP                                | 16   | Select the phase of serial data.<br>It must match the data phase selection by the master.                                    |
| [O] | CSI_CNT       | DMA transfer for transmission: T_DMAEN          | 24   | Determines the method for transfer or data for transmission.                                                                 |
| [O] |               | Transmission FIFO trigger level: T_TRGEN        | 27   | Determines use of the transmission FIFO trigger level.                                                                       |
| [O] |               | DMA transfer for reception: R_DMAEN             | 16   | Determines the method for transfer of received data.                                                                         |
| [O] |               | Reception FIFO trigger level: R_TRGEN           | 19   | Determines use of the reception FIFO trigger level.                                                                          |
| [O] |               | All transmission completed interrupt: TREND_E   | 9    | Determines use of the all transmission completed interrupt.                                                                  |
| [O] |               | Underrun error interrupt: UNDER_E               | 13   | Determines use of the underrun error interrupt.                                                                              |
| [O] |               | Overflow interrupt: OVERF_E                     | 12   | Determines use of the overflow interrupt.                                                                                    |
| [O] |               | Transfer completed interrupt: CSIEND_E          | 8    | Determines use of the transmission completed interrupt.                                                                      |
| [O] |               | Transmission trigger level interrupt: T_TRGR_E  | 4    | Determines use of the transmission trigger level interrupt.                                                                  |
| [O] |               | Reception trigger level interrupt: R_TRGR_E     | 0    | Determines use of the reception trigger level interrupt.                                                                     |
| [O] | CSI_FIFOTRG   | Transmission FIFO trigger level: T_TRG          | 10:8 | Sets the level value when the transmission FIFO trigger level is used.                                                       |
| [O] |               | Reception FIFO trigger level: R_TRG             | 2:0  | Sets the level value when the reception FIFO trigger level is used.                                                          |

Note 1. [R]: Required setting items.  
[O]: Optional. Set these items as required.

### 38.4.10.2 Operation in Slave Transmission/Reception Mode

#### (1) How to Start Operation

After the initial settings, set the startup flag for communications (the CSIE bit in CSI\_MODE) and write data for transmission to the transmission FIFO to prepare for operations for transmission and reception.

The slave starts operations for transmission and reception on reception of the serial clock (SCK) from the master. To use the function for slave selection (SS pin), however, the SS pin must be at the active level before starting transmission and reception.

To start operations for communications with the serial clock output by the master, the initial settings must be completed to start operations for transmission and reception.

#### (2) How to End Operation

Clearing the startup flag for communications (the CSIE bit in CSI\_MODE) stops operations for transmission and reception.

Even if data for transmission remain in the transmission FIFO at the time the startup flag is cleared, operations for transmission and reception are stopped.

If the startup flag is cleared during the cycle of operations for transmission and reception, operations for transmission and reception are stopped after the completion of the cycle.

After operations for transmission and reception are stopped, the slave does not respond to the request for transmission and reception from the master.

The SOOE pin goes to the low level when the CSIE bit is cleared and communications for transmission and reception are stopped.

#### (3) Operation during Communications

The slave handles operations for transmission and reception according to the serial clock transmitted from the master.

If transmission proceeds while the transmission FIFO has no data, an underrun error occurs.

Operations for transmission and reception are stopped if an underrun error occurs.

An overflow error occurs if reception proceeds while the reception FIFO is full.

If an overflow error occurs, reception is stopped, but transmission continues.

For details of underrun and overflow errors, see **Section 38.4.5, Operation and Procedure for Processing when an Error Occurs**.

To avoid an error, control is required to ensure that the transmission FIFO is never empty and the reception FIFO is never full.

#### (4) Reception Trigger Level Interrupt

A reception trigger level interrupt can be used. For details, see **Section 38.4.11.2, Reception Trigger Level**.

This interrupt occurs when received data are accumulated to the value set in R\_TRG of the CSI\_FIFOTRG register.

Reception will continue even if the reception trigger level interrupt occurs.

**(5) Transmission Trigger Level Interrupt**

A transmission trigger level interrupt can be used. For details, see **Section 38.4.11.1, Transmission Trigger Level**.

The transmission trigger level interrupt occurs when data in the transmission FIFO are reduced due to the operation for transmission and the free space increases to the value set in T\_TRG of the CSI\_FIFOTRG register.

Even if this interrupt occurs, transmission and reception continue.

**(6) Communications Error**

An underrun error may occur.

An overflow error may occur.

### **38.4.10.3 Settings in Slave Transmission/Reception Mode and Flow of Operations (for Transmission and Reception)**

The figure below shows a flow of operations for transmission and reception with the use of the transmission trigger level interrupt in slave transmission/reception mode.

Data for transmission prepared in the transmission buffer are continuously transferred with the use of the transmission trigger level interrupt and all transmission completed interrupt.

Figure 38.4-16 Flow of Operations with Interrupt Transfer in Slave Transmission/Reception Mode (for Transmission and Reception) (1/4)

Figure 38.4-16 Flow of Operations with Interrupt Transfer in Slave Transmission/Reception Mode (for Transmission and Reception) (2/4)

Figure 38.4-16 Flow of Operations with Interrupt Transfer in Slave Transmission/Reception Mode (for Transmission and Reception) (3/4)

Figure 38.4-16 Flow of Operations with Interrupt Transfer in Slave Transmission/Reception Mode (for Transmission and Reception) (4/4)

#### **38.4.10.4 Settings in Slave Transmission/Reception Mode and Flow of Operations (for Transmission-only Operation)**

The figure below shows a flow of operations for transmission with the use of the transmission trigger level interrupt in slave transmission/reception mode.

Data for transmission prepared in the transmission buffer are continuously transferred with the use of the transmission trigger level interrupt and all transmission completed interrupt. Since the transmission function is only used, processing of received data is not handled.

Figure 38.4-17 Flow of Operations with Interrupt Transfer in Slave Transmission/Reception Mode (for Transmission-only Operation) (1/4)

Figure 38.4-17 Flow of Operations with Interrupt Transfer in Slave Transmission/Reception Mode (for Transmission-only Operation) (2/4)

Figure 38.4-17 Flow of Operations with Interrupt Transfer in Slave Transmission/Reception Mode (for Transmission-only Operation) (3/4)

Figure 38.4-17 Flow of Operations with Interrupt Transfer in Slave Transmission/Reception Mode (for Transmission-only Operation) (4/4)

### 38.4.11 Trigger Level Function

The CSI has the trigger level function which monitors the buffering level of data for the transmission FIFO and the reception FIFO respectively and generates a trigger in response to the setting.

The trigger level function can be set for transmission and for reception individually.

A trigger can be used as a source of the interrupt request and the DMA transfer request.

#### 38.4.11.1 Transmission Trigger Level

A trigger occurs when the free space in the transmission FIFO reaches the specified level due to the operation for transmission.

##### (1) Setting Procedure

Set the level at which a trigger occurs in T\_TRG[2:0] of the CSI FIFO trigger level register (CSI\_FIFOTRG). Also, setting the transmission trigger level setting enable flag (T\_TRGEN) in the CSI control register (CSI\_CNT) makes the trigger level available. To use the transmission trigger level as an interrupt, set the transmission trigger level interrupt enable flag (T\_TRGR\_E ) in the CSI control register (CSI\_CNT).

If the T\_DMAEN bit in the CSI control register (CSI\_CNT) is set to enable DMA transfer for transmission, the transmission trigger level can be used for the DMA transfer request for transmission.

##### CAUTION

The settings for the transmission trigger level other than the interrupt enable flag should be made while communications are stopped (CSOT bit of CSI\_MODE = 0b). Operation when the settings are made during communications (when CSIE of the CSI\_MODE register = 1b or CSOT = 1b) is not guaranteed.

## (2) Description of Operation

A trigger occurs when the free space in the transmission FIFO reaches the setting of the transmission trigger level (T\_TRG[2:0] in CSI\_CNT).

A trigger does not occur if the setting is exceeded when data for transmission are written to the transmission FIFO and the free space is reduced. A trigger does not also occur when the free space in the transmission FIFO does not fall below the specified level after the occurrence of a trigger. Therefore, to continue transmission by using the transmission trigger level, care should be taken with management of the free space in the transmission FIFO in order to maintain the occurrence of triggers.

To use the transmission trigger level as an interrupt, clear the transmission trigger level interrupt flag (T\_TRGR) in the CSI interrupt status register (CSI\_INT) after writing data for transmission to the transmission FIFO following the occurrence of the transmission trigger level interrupt.

Figure 38.4-18 Operation of the Transmission FIFO when the Transmission Trigger Level is Set

### 38.4.11.2 Reception Trigger Level

A trigger occurs when the buffering level of the reception FIFO exceeds the specified level due to the operation for reception.

#### (1) Setting Procedure

Set the level at which a trigger occurs in R\_TRG[2:0] of the CSI FIFO trigger level register (CSI\_FIFOTRG). Also, setting the reception trigger level setting enable flag (R\_TRGEN) in the CSI control register (CSI\_CNT) makes the trigger level available.

To use the reception trigger level as an interrupt, set the reception trigger level interrupt enable flag (R\_TRGR\_E) in the CSI control register (CSI\_CNT).

If the R\_DMAEN bit in the CSI control register (CSI\_CNT) is set to enable DMA transfer for reception, the reception trigger level can be used for the DMA transfer request for reception.

#### CAUTION

---

The settings for the reception trigger level other than the interrupt enable flag should be made while communications are stopped (CSOT bit of CSI\_MODE = 0b). Operation when the settings are made during communications (when CSIE of the CSI\_MODE register = 1b or CSOT = 1b) is not guaranteed.

---

## (2) Description of Operation

A trigger occurs when the capacity in the reception FIFO reaches the setting of the reception trigger level (R\_TRG[2:0] in CSI\_CNT).

A trigger does not occur if the setting is exceeded when received data are read from the reception FIFO and the amount of received data is reduced. A trigger does not also occur when the amount of data in the reception FIFO does not exceed the specified level after the occurrence of a trigger. Therefore, to continue reception by using the reception trigger level, care should be taken with management of the amount of received data in the reception FIFO in order to maintain the occurrence of triggers.

To use the reception trigger level as an interrupt, clear the reception trigger level interrupt flag (R\_TRGR) in the CSI interrupt status register (CSI\_INT) after reading received data from the reception FIFO following the occurrence of the reception trigger level interrupt.

When the reception trigger level is used for DMA transfer, data may remain in the reception FIFO if the amount of received data in the FIFO falls below the setting at the end of operation.

For the procedure for processing remained data in DMA transfer, see **Section 38.4.14.3, Processing for Reading the Remained Received Data in DMA Transfer**.

Figure 38.4-19 Operation of the Reception FIFO when the Reception Trigger Level is Set

### 38.4.12 Method of Data Transfer

Reading of received data from the CSI and writing of data for transmission proceeds with “interrupt transfer” or “DMA transfer”.

Whichever method of data transfer is used, the trigger level function can be used.

The method of data transfer is selected by using T\_DMAEN and R\_DMAEN of the CSI\_CNT register. The initial setting at the time of a reset is “interrupt transfer”.

### 38.4.13 Interrupt Transfer

In interrupt transfer, the program handles writing of data for transmission to the transmission FIFO and reading of received data from the reception FIFO.

This method of data transfer allows flexible data processing, buffer control, and communications protocol control because data are transferred by the program, though the load on the CPU is greater than that when DMA transfer is used.

For writing of data for transmission, the all transmission completed interrupt (TREND) or transfer completed interrupt (CSIEND) are used.

For reading of received data, the transfer completed interrupt (CSIEND) is used.

In addition, the transmission and reception trigger level interrupts can be used with the use of the trigger level function.

For details of the trigger level function, see **Section 38.4.11, Trigger Level Function**.

### 38.4.14 DMA Transfer

In DMA transfer, the DMA controller handles writing of data for transmission and reading of received data.

This method of data transfer allows reduced CPU load and is suited to transfer large data all at once, though it does not allow flexible control compared with interrupt transfer by the program.

For writing of data for transmission, the transmission DMA request signal (DMAREQTX) is used. For reading of received data, the reception DMA request signal (DMAREQRX) is used. In addition, the transmission and reception trigger level functions can be used respectively for the transmission DMA and reception DMA requests.

DMA transfer can only be used in single transfer mode and cannot be used in block transfer mode.

**Figure 38.4-20** shows an example of connection of the CSI with the DMA controller.

Figure 38.4-20 Basic Connection of the DMAC and the CSI

**Figure 38.4-21** and **Figure 38.4-22** show the timing of interfacing with the DMA controller.

Transfer of data to and from the DMA controller proceeds in single transfer mode. Make settings for the DMA controller such that the DMA request signal and DMA acknowledge signal operate under the following conditions for both reception and transmission.

- The DMA request signals (DMAREQRX, DMAREQTX) are set to level operation mode.
- The DMA transfer mode is set to single transfer mode.
- The DMA response signals (DMAACKRX, DMAACKTX) correspond to cycles for access to the CSI register.

Note 1. The DMAACKRX signal should not be at the low level while the DMAREQRX signal is active.

Note 2. A cycle of reading received data from the DMAC requires a wait for at least two cycles of PCLK after the DMAACKRX signal becomes active.

Note 3. In the case of continuous DMA transfer for reception, an interval time of three or more cycles of PCLK is inserted after the DMAACKRX signal becomes inactive until the next DMAREQRX signal becomes active.

Figure 38.4-21 Timing of DMA Transfer for Reception

Note 1. The DMAACKTX signal should not be at the low level while the DMAREQTX signal is active.

Note 2. A cycle of writing data for transmission from the DMAC requires a wait for at least two cycles of PCLK after the DMAACKTX signal becomes active.

Note 3. In the case of continuous DMA transfer for transmission, an interval time of three or more cycles of PCLK is inserted after the DMAACKTX signal becomes inactive until the next DMAREQTX signal becomes active.

Figure 38.4-22 Timing of DMA Transfer for Transmission

### 38.4.14.1 DMA Transfer for Reception

Following the start of reception, the reception DMA request signal is output when received data are stored in the reception FIFO.

The DMA controller transfers received data to memory from the reception FIFO in response to the DMA request signal.

DMA transfer corresponds to single transfer mode and the reception DMA request signal is output every time one unit of received data is transferred.

DMA transfer for reception operates until the reception FIFO has no data.

#### (1) Startup Procedure

1. When DMA transfer for reception is to be used, set the reception DMA transfer enable flag (R\_DMAEN) of the CSI control register (CSI\_CNT).
2. Set up the DMA controller.
3. Set the startup flag for communications to start reception.

#### (2) End of Operation

The output of the reception DMA request is stopped when communications by the CSI are stopped and all received data in the reception FIFO are read out.

After reception by the CSI is stopped, DMA operation of the DMA controller is stopped.

To end DMA operation after all received data in the reception FIFO are read out, mask the DMA request signal by the DMA controller so as not to accept the subsequent DMA request from the CSI before stopping the CSI by a CSI reset.

Operation when a CSI reset is applied during DMA operation is not guaranteed.

#### (3) Restarting DMA Transfer

Transfer by the DMA controller is completed when the numbers of data transfers specified in the DMA controller are completed. However, the CSI continues to output the DMA request for reception as long as there are received data, so proceed with restarting the DMAC to continue data transfer.

#### (4) Reception Trigger Level

The reception trigger level function can also be used for control of DMA transfer. For the setting of the trigger level function, see **Section 38.4.11.2, Reception Trigger Level**.

In DMA transfer for reception, when the reception trigger level is set, the reception DMA request signal is output when the amount of data in the reception FIFO reaches the trigger level.

The reception DMA request signal transfers data the number of times set as the trigger level.

When the reception trigger level is used, if the amount of data in the reception FIFO is less than the setting of the trigger level on completion of communications by the CSI, the data remain in the FIFO.

Regarding processing for reading of remained data, see **Section 38.4.14.3, Processing for Reading the Remained Received Data in DMA Transfer**.

### 38.4.14.2 DMA Transfer for Transmission

Following the start of transmission, the transmission DMA request signal is output if the transmission FIFO has space.

The DMA controller transfers data for transmission to the transmission FIFO from memory in response to the DMA request signal.

DMA transfer corresponds to single transfer mode and the transmission DMA request signal is output every time one unit of data for transmission is written.

In DMA transfer, data transfer continues as long as the transmission FIFO has space.

#### (1) Startup Procedure

1. When DMA transfer for transmission is to be used, set the transmission DMA transfer enable flag (T\_DMAEN) of the CSI control register (CSI\_CNT).
2. Set up the DMA controller.
3. Set the startup flag for communications to start transmission.

#### (2) End of Operation

The output of the transmission DMA request is stopped when communications by the CSI are stopped and data are written to the transmission FIFO and it has no space.

After transmission by the CSI is stopped, DMA operation of the DMA controller is stopped.

To transmit data remained in the transmission FIFO, restart communications by the CSI and wait until the FIFO is empty.

In addition, if the transmission DMA transfer request can be masked by the DMA controller, stop the DMA controller before stopping communications, then send all data in the transmission FIFO and stop communications.

#### (3) Restarting DMA Transfer

Transfer by the DMA controller is completed when the numbers of data transfers specified in the DMA controller are completed. However, the CSI continues to output the DMA request for transmission as long as the transmission FIFO has space, so proceed with restarting the DMAC to continue data transfer.

#### (4) Transmission Trigger Level

The transmission trigger level function can also be used for control of DMA transfer. For the setting of the trigger level function, see **Section 38.4.11.1, Transmission Trigger Level**.

When the transmission trigger level is set, the transmission DMA request signal is output when the free space in the transmission FIFO is equal to or greater than the trigger level.

The transmission DMA request signal by the transmission trigger level transfers data the number of times set as the trigger level.

If the free space in the FIFO does not reach the trigger level due to the transmission proceeding while data are transferred to the transmission FIFO by the DMA controller, data are further transferred the number of times set as the trigger level.

### 38.4.14.3 Processing for Reading the Remained Received Data in DMA Transfer

In DMA transfer of received data, the DMA controller reads the amount of received data set as the trigger level from the reception FIFO by the DMA controller. Therefore, data newly received during DMA transfer remain in the FIFO until DMA transfer is completed once and the amount of data reaches the trigger level the next time.

If the amount of data in the FIFO does not reach the trigger level on completion of communications, the received data remain in the FIFO. In such cases, the remained received data can be read through the following processing procedure.

#### (1) Processing for Reading in DMA Transfer (Changing the Trigger Level Setting to the Disabled Setting)

If data remain in the reception FIFO, disabling the trigger level setting asserts DMAREQRX and the remained data are transferred by the DMAC.

The following shows the procedure.

1. Check that the communications state flag of the CSI indicates that communications are stopped (CSOT in CSI\_MODE is 0b).
2. Disable the reception FIFO trigger level setting (R\_TRGEN in CSI\_CNT = 0b).
3. Wait until DMA transfer by the DMA controller is completed.
4. Check that the value of the CSI reception FIFO level indication register (CSI\_IFIFOL) is 0b.

#### (2) Processing for Reading by the Program

The received data are read from the CSI reception window register (CSI\_IFIFO) until the value of the CSI reception FIFO level indication register becomes 0 and the data are written to the reception buffer. Since the DMAC is not used, management of the buffer is required.

The following shows the procedure.

1. Check that the communications state flag of the CSI indicates that communications are stopped (CSOT in CSI\_MODE is 0b).
2. Repeat the following operations until the value of the CSI reception FIFO level indication register (CSI\_IFIFOL) becomes 0b.
3. Read the received data from the CSI reception window register (CSI\_IFIFO).
4. Write the read data to the reception buffer.

#### **38.4.14.4 Settings in Master Transmission/Reception Mode with the Use of DMA Transfer and Flow of Operations**

The figure below shows example settings and a flow of operations when DMA transfer is used in master transmission/reception mode

For the specifications of the registers of the DMAC, refer to the section of DMAC.

Figure 38.4-23 Flow of Operations of DMA Transfer in Master Transmission/Reception Mode (Continuous Data Transmission) (1/3)

Figure 38.4-23 Flow of Operations of DMA Transfer in Master Transmission/Reception Mode (Continuous Data Transmission) (2/3)

Figure 38.4-23 Flow of Operations of DMA Transfer in Master Transmission/Reception Mode (Continuous Data Transmission) (3/3)

## 38.5 Timing Chart

### 38.5.1 Timing of Serial Communications (Single-Word Transfer)

The following shows the timing of operation for single-word transfer.

**Figure 38.5-1** is a timing chart for transmission and reception of a single unit of data.

#### <Operating Conditions>

- Data length: 8 bits
- MSB Start of data: MSB
- Polarity of the clock: High level
- Phase of data: The same phase as that of SCK
- Data for transmission: 8Bh
- Data for reception: A6h

Figure 38.5-1 Timing of Single-Word Transfer (in Master Transmission/Reception Mode)

**Figure 38.5-2** is a timing chart for transmission and reception of a single unit of data in master transmission/reception mode.

### <Operating Conditions>

- Data length: 8 bits
- Start of data: MSB
- Polarity of the clock: High level
- Phase of data: Half a cycle after SCK
- Data for transmission: 8Bh
- Data for reception: A6h

Figure 38.5-2 Timing of Single-Word Transfer (in Master Transmission/Reception Mode)

**Figure38.5-3** is a timing chart for transmission and reception of a single unit of data in slave transmission/reception mode.

### <Operating Conditions>

- Data length: 8 bits
- Start of data: MSB
- Polarity of the clock: High level
- Phase of data: The same phase as that of SCK
- Data for transmission: A6H
- Data for reception: 8BH

Figure38.5-3 Timing of Single-Word Transfer (in Slave Transmission/Reception Mode)

### 38.5.2 Timing of Serial Communications (Continuous Data Transfer)

The figure below shows the timing of operation for continuous data transfer.

Figure 38.5-4 Timing of Continuous Transfer (in Master Reception-only Mode)

Figure 38.5-5 Timing of Continuous Transfer (in Master Transmission/Reception Mode)

When the startup flag for communications is set, the transmission DMA request signal (DMAREQTX) is asserted to start DMA transfer.

Writing the first data to the transmission FIFO buffer with DMA transfer starts operations for transmission and reception.

When DMA transfer of data for transmission is completed, wait for the completion of transmission and poll the communications state flag (CSOT).

Check that communications are stopped by reading the communications state flag and clear the startup flag for communications (CSIE).

Clearing the startup flag for communications (CSIE) de-asserts the transmission DMA request signal (DMAREQTX).

Figure 38.5-6 Timing of Continuous Transfer (in Slave Transmission/Reception Mode)

When the startup flag for communications is set, if the transmission FIFO has space, the transmission DMA request signal (DMAREQTX) is asserted to start DMA transfer.

Writing the first data to the transmission FIFO buffer with DMA transfer completes preparation for starting operations for transmission and reception.

Operations for transmission and reception start when the slave selection pin (SS) is asserted by the master and the serial clock (SCKI) is input.

Note that the slave selection signal requires at least four PCLK cycles of the setup time relative to the timing for starting communications. If a sufficient setup time is not secured, bit shifting of transfer data occurs and data may be destroyed.

Operations for transmission and reception are stopped when the slave selection signal is de-asserted.

To complete operations for communications by the slave, check that operations for transmission and reception have been stopped by reading the communications state flag (CSOT) and then clear the startup flag (CSIE).

Clearing the startup flag for communications (CSIE) de-asserts the transmission DMA request signal (DMAREQTX).

## 38.6 Usage Notes

### 38.6.1 Notes on the Communications Speed

The following illustrates an example with the polarity of the clock and the phase when the CKP bit = 0 and the DAP bit = 0 in the CSI\_CLKSEL register. In the case of other settings, consider the case with the polarity of the clock and the phase corresponding to these settings.

Figure 38.6-1 Master and Slave Connection

Figure 38.6-2 Timing of Data Reception by the Master

Serial data (SI) are sampled by the master on the edge of half a cycle of the serial clock (SCKO).

**Figure 38.6-2** shows the timing of data reception by the master.

The slave outputs data for transmission to the SO pin on rising edges of the serial clock SCK signal from the master.

The master captures data for transmission from the slave on rising edges of SCK.

Calculate the highest frequency of the serial clock from the time which is required for the master to receive serial data from the slave.

$$\frac{\text{Serial clock frequency}}{2} > t_{DLA} + T_{pd} + t_{DLB} + T_{su}$$

$t_{DLA}$ : Delay of output buffer A and input buffer B and signal delay in the transmission path of SCK

$T_{pd}$ : Delay of SO from SCKI of the slave

$t_{DLB}$ : Delay of output buffer C and input buffer D and signal delay in the transmission path of SO

$T_{su}$ : Setup time for data from the master

When the serial clock is used at 25 MHz, design such that the above value is within 20 ns.

## Section 39 Universal Asynchronous Receiver/Transmitter (UART)

This section describes the functions of a universal asynchronous receiver/transmitter (UART).

### 39.1 Overview

The UART includes two 64-byte FIFO buffers, one for transmission and has functional compatibility with the general-purpose 16750 UART chip.

This LSI has two channels of UART, ch. 0 and ch. 1. Of those, ch. 1 is for use with the ISP support package, so do not use registers related to this channel.

In addition, DMAC is for use with the ISP support package, so do not use the DMA transfer using the DMA interface of the UART.

#### 39.1.1 Features

- Register-compatible with the general-purpose 16750 UART chip
- Two 64-byte FIFO buffers are included, one for transmission and one for reception. One of the following operating modes is selectable by settings.
  - Non-FIFO mode (16450 mode)
  - 16-byte FIFO mode (16550 mode)
  - 64-byte FIFO mode
- The reception FIFO buffer includes a 3-bit (PE: Parity error, FE: Framing error, BI: Break interrupt) error data register.
- Programmable auto-RTS and auto-CTS are supported.  
(DSR, DTR, RI, and DCD are not supported.)
- Start, stop, and parity bits as the standard asynchronous transfer control bits can be appended to serial data for transmission and handled in received data. The following forms of programmable control are available.
  - Character length control: 5, 6, 7, or 8 bits
  - Parity bit control: Even, odd, or no parity
  - Stop-bit length control: 1 or 2 bits
  - Baud rate control: The on-chip baud rate generator allows selection of the desired bit rate.  
Supports major baud rates (such as 9600 bps, 19200 bps, 38400 bps, 57600 bps, and 115200 bps)
- CTS and RTS are supported for the modem control interface.
- Various status registers and an interrupt generation circuit with priority control are included.
- DMA interface supported
- Loopback function supported
- Asynchronous clock signals can be input as the bus clock and serial clock signals.

- The frequency of the bus clock (PCLK) must be greater than the frequency of the bit-rate generator output clock (the clock signal produced by frequency dividing the serial clock (SCLK)).
- 1-bit sampling in 16 clock cycles of the bit-rate generator output clock

39.1.2 Connection Configuration

Figure 39.1-1 shows the connection configuration of the UART.

Figure 39.1-1 Connection Configuration

## 39.2 Pin Functions

### 39.2.1 List of Internal Pins

**Table 39.2-1** lists the internal pins of the UART.

Table 39.2-1 List of Interface Pins

| Classification        | Pin name   | I/O    | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------|------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Serial Interface Pins | CTS_N      | Input  | Modem status signal (Clear to Send)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                       | SIN        | Input  | Serial data input                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                       | RTS_N      | Output | Transmission request signal for modem control (Request to Send)                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                       | SOUT       | Output | Serial data output<br>After a reset, the high level is output when operation is in loopback mode.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                       | SCLK       | Input  | Serial clock input for baud-rate generation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| DMA Interface Pins    | DMA_TX_REQ | Output | DMA request signal for transmission. The high level is output when a DMA request is issued.<br>There are two DMA modes for the FIFO buffer when it is in use. One is for single DMA transfers and the other is for multiple DMA transfers. Either is selectable. For details, see <b>Section 39.3.2.4, FIFO Control Register (URTm_FCR) (m = 0, 1))</b> .                                                                                                                                                                             |
|                       | DMA_RX_REQ | Output | DMA request signal for reception. The high level is output in response to a DMA request.<br>When the FIFO buffer is in use, either of the two DMA modes is selectable as with transmission. For details, see <b>Section 39.3.2.4, FIFO Control Register (URTm_FCR) (m = 0, 1))</b> .                                                                                                                                                                                                                                                  |
| Interrupt Pin         | INTR       | Output | Interrupt (level output). The high level is output when any of the following interrupt source conditions is satisfied.<br><br>[Interrupt sources]<br>1) Reception error<br>2) Completion of the reception or a timeout (only when the FIFO buffer is in use)<br>3) The transmission buffer being empty<br>4) Modem status<br><br>Which interrupt sources to include is controllable by the interrupt enable register, IER. The INTR signal is reset to the low level from within the given interrupt processing or by a master reset. |

### 39.3 Register Descriptions

For the register base addresses (<URT0\_S0\_base> and <URT1\_S0\_base>), see the section Address Map.

#### 39.3.1 List of Registers

The registers are readable and writable in 32-bit units, but only the 8 lower-order bits are actually functional (so 1-byte access is equally effective) as shown in **Table 39.3-2**.

Table 39.3-1 List of Registers

| DLAB (LCR[7])* <sup>1</sup> | Offset Address | Register Name                                                 | Abbreviation | Initial Value | Access Unit (bits) |
|-----------------------------|----------------|---------------------------------------------------------------|--------------|---------------|--------------------|
| x                           | 00h            | Receiver Buffer Register (when reading received data)         | URTm_RBR     | 0000_0000h    | 32                 |
|                             |                | Transmitter Holding Register (when writing transmission data) | URTm_THR     | 0000_0000h    | 32                 |
| x                           | 04h            | Interrupt Enable Register                                     | URTm_IER     | 0000_0000h    | 32                 |
| x                           | 08h            | Interrupt Ident. Register                                     | URTm_IIR     | 0000_0001h    | 32                 |
| x                           | 0Ch            | FIFO Control Register                                         | URTm_FCR     | 0000_0000h    | 32                 |

**Note:** x: Don't care; m = 0, 1

Note 1. LCR7: Bit 1 in the line control register

For the setting, see **Section 39.5, Procedure**. When LCR[7] is set to 0b, access to DLL and DLM is disabled and generation of a 16x baud rate clock is started.

Note 2. The reserved area is not used. It is always read as 0b.

Note 3. Access to the RFU area is prohibited.

Table 39.3-2 List of Registers (Detail) (1/2)

| Offset Address     | Register Name                                         | Description                       |                                 |                             |                                           |                                     |                                       |                                              |                                                             |                                                           |

**Note:** m = 0, 1

Note 1. Unused bits. Writing to these bits has no effect.

Note 2. Unused bits. However, these bits are readable and writable.

Note 3. Access to these bits is prohibited.

Note 4. Unused bits. These bits are always read as 0b.

Note 5. Unused reserved area. Writing to this area has no effect. It is always read as 0b.

### 39.3.2 Register Descriptions

The function description of each register is given below.

The prefix (URTm\_) of the register names is omitted in the register descriptions and the field descriptions in this section.

#### 39.3.2.1 Receiver Buffer Register (when reading received data) (URTm\_RBR) / Transmitter Holding Register (when writing transmission data) (URTm\_THR) (m = 0, 1)

This register is a received data reading/transmitting data writing register. In FIFO mode (FCR[0] = 1b), an access target is FIFO.

**Access Size:** 32 bits

**Address(es):** <URT0\_S0\_base> + 0000h  
<URT1\_S0\_base> + 0000h

**Initial Value:** 0000\_0000h

| 7 to 0       | DATA[7:0] | <ul style="list-style-type: none"> <li>Non-FIFO mode (FCR[0]=0b)<br/>Reading address 00h will read the data from the RBR, and writing will store the data to THR. The first bit received or transmitted is the data bit[0] of LSB. Both RBR and THR are the 1-byte registers on implementation.</li> <li>FIFO mode (FCR[0]=1b)<br/>Reading address 0 will read the data from the receive FIFO, and writing will store the data to the transmit FIFO.<br/>Selecting the size of FIFO with FCR[5]. If FCR[5]=0b, the FIFO size is 16 bytes (16550 mode), and if FCR[5]=1b, the FIFO size is 64 bytes.</li> </ul> <p><b>Note:</b> When writing to the transmit FIFO full of data, an overrun is detected and the transmit FIFO will not be written. When an overrun is detected, status register HCR3[7] is set to high. When reading from receive FIFO empty of data, and underrun is detected and the FIFO will not be read (all read as 0b). When an underrun is detected, status register HCR2[7] is set to high.</p> <p>When the received or transmitting data is less than 8 bits (5, 6, or 7 bits), lower bits are received or transmitted and upper bits exceeding the set transfer bit count are discarded.</p> <p>(Ex) When the amount of transfer data is set as 5 bits (LCR[1:0]=00b), on the transmit side, the data bits 0 to 4 are transmitted and data bits 7 to 5 are discarded. On the receive side, the valid data to bits 4 to 0 and 0 to the data bits 7 to 5 are written.</p> |

### 39.3.2.2 Interrupt Enable Register (URTM\_IER) (m = 0, 1)

This register enables an interrupt. Set each interrupt factor individually. Setting 1b enables the corresponding interrupt. (See URTm\_IIR about the detail of the interrupt factors, the releasing interrupt conditions, the priority of the interrupt factors.)

**Access Size:** 32 bits

**Address(es):** <URT0\_S0\_base> + 0004h  
<URT1\_S0\_base> + 0004h

**Initial Value:** 0000\_0000h

Table 39.3-4 URTm\_IER Register Contents

| Bit Position | Bit Name | Description                                                               |
|--------------|----------|---------------------------------------------------------------------------|
| 31 to 8      | —        | Reserved. These bits are read as 0b.                                      |
| 7 to 4       | —        | Reserved. These bits are read as 0b. The write value should be always 0b. |
| 3            | EDSSI    | Enable Modem Status Interrupt.                                            |
| 2            | ELSI     | Enable Receiver Line Status Interrupt.                                    |
| 1            | ETBEI    | Enable Transmitter Holding Register (THR) Empty Interrupt.                |
| 0            | ERBI     | Enable Received Data Available/ time-out Interrupt.                       |

*Note:* Receive complete and timeout may be excluded from the interrupt factor with IER[0]=0b. When HCR0[4]=1b (time-out DMA REQ disable), regardless of the setting of IER[0], a timeout is added to the interrupt factor.

**Note:** Timeout detecting condition: When there is at least one character in the FIFO, with the following condition 1 or 2 met, a timeout is detected.

- The received latest 4 serial characters are before character-time consecutively.
- The 4 latest FIFO readings are before character-time consecutively.

4 consecutive character-time = 768 cycles of BAUDOUT\_N

4 characters of 12-bit received character (1-bit start, 8-bit data, 1-bit parity, 2-bit stop) (12 × 4 × 16 = 768 cycles of BAYDIYT\_N)

39.3.2.3 Interrupt Identification Register (URTm\_IIR) (m = 0, 1)

This register is a read-only interrupt identification register. This register identifies the operation mode (bits 7 to 5) and the interrupt factor (bits 3 to 0).

When multiple interrupt factors occur, this register outputs the priority processed result.

Note 1. If the DMA reads the FIFO when a reception complete or timeout interrupt occurs, that interrupt factor (reception complete or timeout) information is overwritten and the interrupt factor becomes "None". (When the status is confirmed by the system F/W, it may look like "None". Ignore a "None" interrupt in that situation, and control that situation.)

Note 2. See Line Status Register (LSR) about the detection conditions of Overrun/Framing Error/Break Interrupt.

Note 3. See Modem Status Register (MSR) about the detection conditions of  $\Delta$ CTS/ $\Delta$ DSR/ $\Delta$ DCD/Trailing Edge RI. It will not be in a state other than the above.

Note 4. The interrupt of transmit buffer empty (IIR[3:0] = 0010b) is cleared by either

- Reading IIR
- Writing data to THR

Specifically, the operation of 1 as follows.

If the transmit buffer is empty when IIR is read to check the interrupt cause, it is masked by the read operation and this interrupt will not occur. This mask is cleared when data is written to the transmit buffer, and subsequent transmit buffer empty interrupts are output.

### 39.3.2.4 FIFO Control Register (URTm\_FCR) (m = 0, 1)

This register controls FIFO.

**Access Size:** 32 bits

**Address(es):** <URT0\_S0\_base> + 000Ch  
<URT1\_S0\_base> + 000Ch

**Initial Value:** 0000\_0000h

Table 39.3-7 URTm\_FCR Register Contents (2/2)

| Bit Position | Bit Name               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2            | Transmitter FIFO Reset | <p>Transmitter FIFO Reset</p> <p>When set to “1b”, the synchronized reset pulse (1 cycle of PCK) is generated, and then reset the whole byte of the transmit FIFO, and the FIFO address counter. This bit is automatically reset to “0”.</p> <p><i>Note:</i> The transmit shift-register TSR is not reset. Therefore, if it is reset during transmission, transmission of data in the shift register is completed and one more “0” frame may be transmitted.</p> |
| 1            | Receiver FIFO Reset    | <p>Receiver FIFO Reset</p> <p>When set to “1b”, the synchronized reset pulse (1 cycle of PCK) is generated, and then reset the whole byte of the receive FIFO, and the FIFO address counter. This bit is automatically reset to “0”.</p> <p><i>Note:</i> The receive shift-register RSR is not reset. Therefore, if it is reset during reception, the data being received is stored in the receive FIFO normally.</p>                                            |
| 0            | FIFO Enable            | <p>FIFO Enable</p> <p>Set to “1b”, both transmission and reception are in FIFO mode.</p> <p>Set to “0b”, both transmission and reception are in non-FIFO mode.</p>                                                                                                                                                                                                                                                                                               |

Table 39.3-8 DMA Mode and DMA Request Generation Condition

| Mode                                    |        | DMA Request Generation Condition                             | DMA Request Releasing Condition                         |
|-----------------------------------------|--------|--------------------------------------------------------------|---------------------------------------------------------|
| DMA access data width 1 byte (HCR[5]=0) |        |                                                              |                                                         |
| Receive DMA request                     | Mode 0 | There is more than 1 byte of data in the receive FIFO        | The receive FIFO is empty.                              |
|                                         | Mode 1 | The receive FIFO trigger level reached or time-out occurs.*1 | The receive FIFO is empty.                              |
| Transmit DMA request                    | Mode 0 | The transmit FIFO is empty.                                  | There is more than 1 byte of data in the transmit FIFO. |
|                                         | Mode 1 | The transmit FIFO is empty.                                  | The transmit FIFO is full.                              |

Note 1. Timeout may be excluded from the receive DMA condition with setting HCR0[4].

Note 2. Performs operation equivalent to mode 0 in non-FIFO mode regardless setting FCR[3], HCR0[3:2].

- Receive DMA request: When 1-byte data receiving in the receive buffer register is completed, the DMA request occurs.
  - Clear the request, when the register is empty.
- Transmit DMA request: When the transmit buffer is empty, the DMA request occurs. Clear the request, when there is 1-byte data.

### 39.3.2.5 Line Control Register (URTm\_LCR) (m = 0, 1)

This register controls the FIFO.

**Access Size:** 32 bits

**Address(es):** <URT0\_S0\_base> + 0010h  
<URT1\_S0\_base> + 0010h

**Initial Value:** 0000\_0000h

| 0            | x            | x                  | —        | —                             |

**Note:** x: Don't care    ●: Enable    —: Disable

#### Auto-CTS operation:

While input terminal CTS\_N is at the low level (transmit request), the data in the transmit buffer (THR/transmit FIFO) is transmitted. When CTS\_N becomes high, transmission is stopped. During transmission, if CTS\_N changes from high to low, the data in transmission (rest data in shift-register) will be sent, and the next data is stopped from being transmitted.

#### Auto-RTS operation (Valid only in FIFO mode):

- Auto-RTS mode 0

When the amount of the data in the receive FIFO reaches the trigger level, the output terminal RTS\_N is set to the high level (transmission stop request). After the receive FIFO data is read and becomes empty, it is set to the low level (transmission request).

- Auto-RTS mode 1

- 16-byte FIFO: When the amount of data in the receive FIFO is more than 14 bytes, RTS\_N is set to the high level, and when less than 13 bytes, it is set to the low level.
- 64-byte FIFO: When the amount of data in the receive FIFO is more than 56 bytes, RTS\_N is set to the high level, and when less than 55 bytes, it is set to the low level.

#### NOTE

- When auto flow operation is not used, hardware flow control is not performed. Therefore, monitoring CTS and RTS by software is required to prevent FIFO overrun.
- When auto flow is not used (MCR[5] = 0b), MCR[1] is an RTS\_N output software control bit (the inverted level of the MCR[1] setting value is output to RTS\_N).
- If both the modem status interrupt (IER[3] = 1b) and auto-CTS are set, the auto-CTS function is disabled.
- In non-FIFO mode, the auto-RTS function is disabled.

### 39.3.2.7 Line Status Register (URTm\_LSR) (m = 0, 1)

This register checks the transmission/reception status.

**Access Size:** 32 bits

**Address(es):** <URT0\_S0\_base> + 0018h  
<URT1\_S0\_base> + 0018h

### 39.3.2.8 Modem Status Register (URTM\_MSR) (m = 0, 1)

This register is the status register of the control signals connected to Modem (or the peripheral devices).

**Access Size:** 32 bits

**Address(es):** <URT0\_S0\_base> + 001Ch

<URT1\_S0\_base> + 001Ch

**Initial Value:** 0000\_0000h

| 31 to 8      | —        | Reserved. These bits are read as 0b.                                                                            |
| 7 to 0       | SCR      | This 8-bit read/write register has no effect on unit control. This register may be freely used for programming. |

39.3.2.10 Divisor Latch LS Byte Register (URTm\_DLL) (m = 0, 1)

This register is the lower 8 bits (bits 7 to 0) of the divisor setting for the baud rate generator.

The baud rate generator uses this divisor setting value to divide the reference clock (SCLK) to generate a 16x baud rate clock for the transceiver. For divisor settings, two 8-bit registers (DLM, DLL) are used.

| Bit Position | Bit Name | Description                                                                        |
|--------------|----------|------------------------------------------------------------------------------------|
| 31 to 8      | —        | Reserved. These bits are read as 0b.                                               |
| 7 to 0       | DLL      | The lower 8 bits (bits 7 to 0) of the divisor setting for the baud rate generator. |

**Note:** LCR[7] shall be set to 1b before setting DLL and DLM and after writing DLM, DLL LCR[7] shall be set to 0b. See **Section 39.3.2.5, Line Control Register (URTm\_LCR) (m = 0, 1)** for details.

39.3.2.11 Divisor Latch MS Byte Register (URTm\_DLM) (m = 0, 1)

This register is the upper 8 bits (bits 15 to 8) of the divisor setting for the baud rate generator.

The baud rate generator uses this divisor setting value to divide the reference clock (SCLK) to generate a 16x baud rate clock for the transceiver. For divisor settings, two 8-bit registers (DLM, DLL) are used.

Table 39.3-17 URTm\_DLM Register Contents

| Bit Position | Bit Name | Description                                                                         |
|--------------|----------|-------------------------------------------------------------------------------------|
| 31 to 8      | —        | Reserved. These bits are read as 0b.                                                |
| 7 to 0       | DLM      | The upper 8 bits (bits 15 to 8) of the divisor setting for the baud rate generator. |

**Note:** LCR[7] shall be set to 1b before setting DLL and DLM and after writing DLM, DLL LCR[7] shall be set to 0b. See **Section 39.3.2.5, Line Control Register (URTm\_LCR) (m = 0, 1)** for details.

The setting value is as follows. Note that the range of the divisor setting is from 1 to  $2^{16}-1$ . The setting example is indicated in table “Divisor Setting Example”.

$$\text{The setting value of divisor} = \frac{\text{the frequency of the reference clock [Hz]}}{\text{request baud rate [bps]} \times 16}$$

Table 39.3-18 Divisor Setting Example (DLM/DLL)

| Request Baud Rate [bps] | Reference Clock (SCLK) 48 MHz |                      |           |
|-------------------------|-------------------------------|----------------------|-----------|

**Note:** The specifications listed in this table are all theoretical values by design.

### 39.4.2 UART Serial Protocol

The UART serial protocol is briefly described. Serial communications between this UART and an other-party UART device proceed asynchronously. The format of UART serial data is as shown below. Additional bits such as start and stop bits are appended to the first and last of serial data. **Figure 39.4-2** shows the structure of serial data with start and stop bits.

Figure 39.4-2 Structure of Serial Data

A parity bit may be appended to serial data. This bit is effective for simple error checking of received data in communications by the UART. It is appended before the stop bit of transferred data and after the last of the data. UART communications can be controlled by the line control register (LCR register). Data are transmitted from the LSB after the start bit. Optional parity bits and one or two stop bits can be used (this UART does not support half-stop when 1.5 stop bits are used). All bits are transmitted with the same timing.

The communications time for 1-bit data is a clock signal at 16x the baud rate. Once a start bit is detected, received data are sampled almost in the middle of the communications time for each bit of data so that stability is secured for the received data. After the time of sampling in the middle of the start bit, bits are sampled every 16 cycles of the baud rate clock. **Figure 39.4-3** shows the timing of sampling of the first two bits of serial data.

Figure 39.4-3 Serial Data Sampling Timing

The baud rate is controlled by the serial clock and the divisor latch registers (DLH and DLL). The relation between the setting of the divisor latch register and the baud-rate clock is described in **Section 39.3.2.10, Divisor Latch LS Byte Register (URTm\_DLL) (m = 0, 1)** and **Section 39.3.2.11, Divisor Latch MS Byte Register (URTm\_DLM) (m = 0, 1)**.

### 39.4.3 Interrupt

When an interrupt occurs, NTR is asserted. There are interrupt sources as listed below and each interrupt can be enabled by the IER register (bits 3 to 0).

- Reception error
- When data is received
- Character timeout (for use in FIFO mode)
- The transmission data hold register being empty
- Modem status

The interrupt source can be analyzed by referring to the IIR register. Proceed with the appropriate processing according to the given interrupt source.

Table 39.4-2 Interrupt Setting and Clearing Conditions

| IIR Register<br>(Bits 3 to 0) |    |    |    | Interrupt Setting and Clearing Conditions |                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                                     |
|-------------------------------|----|----|----|-------------------------------------------|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|

### 39.4.4 DMA Interface

This unit has a reception DMA request signal (DMA\_RX\_REQ) and a transmission DMA request signal (DMA\_TX\_REQ) to support the DMA interface.

#### 39.4.4.1 DMA Modes of UART

The conditions for issuing and clearing of the DMA request in this unit are selectable from DMA modes, (1) to (3) for reception and (4) to (6) for transmission, as listed in **Table 39.4-3**. For the flow of DMA transfer in each mode, see **Section 39.5, Procedure**.

Operation in non-FIFO mode is equivalent to that in mode 0. The register settings when the FIFO buffer is in use are described in **Section 39.3.2.4, FIFO Control Register (URTm\_FCR) (m = 0, 1)**.

Table 39.4-3 List of DMA Modes of UART

| DMA Mode     |              | DMA Request Issuing Condition                                                    | DMA Request Clearing Condition                               | DMA Transfer Flow    |
|--------------|--------------|----------------------------------------------------------------------------------|--------------------------------------------------------------|----------------------|
| Reception    | (1) Non-FIFO | Completion of the reception of one byte of data in the reception buffer register | The reception buffer being empty                             | <b>Figure 39.5-1</b> |
|              | (2) Mode 0   | The reception FIFO containing one or more bytes of data                          | The reception FIFO being empty                               | <b>Figure 39.5-2</b> |
|              | (3) Mode 1   | The reception FIFO triggering level being reached or occurrence of a timeout     |                                                              | <b>Figure 39.5-3</b> |
|              |              | The FIFO triggering level being reached                                          |                                                              | <b>Figure 39.5-4</b> |
| Transmission | (4) Non-FIFO | The transmission buffer being empty                                              | The transmission buffer register containing one byte of data | <b>Figure 39.5-5</b> |
|              | (5) Mode 0   | The transmission FIFO being empty                                                | The transmission FIFO containing one or more bytes of data   | <b>Figure 39.5-6</b> |
|              | (6) Mode 1   |                                                                                  | The transmission FIFO being full*1                           | <b>Figure 39.5-7</b> |

Note 1. Since the condition for clearing of the DMA request is the transmission FIFO being full, this mode cannot be used except with the per-byte transfer setting.

### 39.4.4.2 Initialization of the DMAC

This section describes operations for DMA transfer. For the detailed DMAC setup procedures, see the section of DMAC.

- The DMA interface of this unit only has a DMA request signal for transmission and reception, so select level detection mode for the detection of DMA transfer requests and bus cycle output mode for the acknowledge output function.
  - DMA transfer request:      Level detection mode
    - Set the LVL bit in the DMAA\_DMAn\_CHCFG\_m register of the DMAC to 1b.
  - DMA acknowledge output:      Bus cycle output mode
    - Set the AM[2:0] bits in the DMAA\_DMAn\_CHCFG\_m register of the DMAC to 010b.
- In bus cycle output mode, the DMA acknowledge signal (DMAACK) is at the active level during the bus cycle periods. If DMAREQ is asserted at the point where a bus cycle is completed, it is handled as a next DMA transfer request.

In level output mode, the DMA request signal and the DMA acknowledge signal are handled as a handshake interface, they must be de-asserted at the same time once before the next DMA request.

39.4.4.3    Timing Comparison of Mode 0 and Mode 1 in DMA Transfer for Reception by This Unit

**Figure 39.4-4** shows an example of timing comparison of (2) Mode 0 and (3) Mode 1 listed in **Table 39.4-3, List of DMA Modes of UART**, in DMA transfer for reception. In this example, a period difference indicated by ★ is generated at the time when transfer of received data is completed.

Figure 39.4-4    Example Comparison of Mode 0 and Mode 1 in DMA Transfer for Reception

#### 39.4.4.4 Timing of DMA Transfer for Reception with the Use of the DMAC

Figure 39.4-5 shows an example of the timing of DMA transfer for reception when the DMAC is in use.

Figure 39.4-5 Example Timing of DMA Transfer for Reception

- The DMAACK signal of the DMAC is at the active level during the period from the time a read request is output to the host bus until one cycle after the last of the read data.
- The DMA transfer request signal (DMA\_RX\_REQ) of the UART becomes inactive level before de-assertion of the DMAACK signal of the DMAC, so DMA transfer proceeds normally.

### 39.4.4.5 Timing of DMA Transfer for Transmission with the Use of the DMAC

Figure 39.4-6 shows an example of the timing of DMA transfer for transmission when the DMAC is in use.

Figure 39.4-6 Example Timing of DMA Transfer for Transmission

- The DMAACK signal of the DMAC is at the active level during the period from the time a write request is output to the host bus until one cycle after a response for the last of the data is returned.
- The DMA transfer request signal (DMA\_TX\_REQ) of the UART becomes inactive level before de-assertion of the DMAACK signal of the DMAC, so DMA transfer proceeds normally.

#### CAUTION

- Writing by the DMAC with the bufferable attribute to the FIFO buffer may proceed after DMAACK is at the inactive level. In such cases, de-assertion of DMA\_TX\_REQ may be delayed and as such the DMAC may mistakenly take DMA\_TX\_REQ to be a next DMA request and proceed with unnecessary transfer.
- To prevent this, use the non-bufferable attribute for writing by the DMAC.

### 39.4.4.6 DMA Request Timing for Reception

Figure 39.4-7 shows the DMA request timing for reception by this unit.

Figure 39.4-7 DMA Request Timing for Reception

Table 39.4-4 DMA Request Timing for Reception

| Symbol                | Parameter                                                                                                      | Figure               | Min. | Typ. | Max. | Unit            | Remarks                                             |

**Note:** The specifications listed in this table are all theoretical values based on RTL.

## 39.5 Procedure

### 39.5.1 Initialization of the UART

The following describes the basic initialization procedures which are required to operate this unit.

1. Input PRESETn (master reset).

↓

2. Set the baud rate.

LCR[7] = 1b      Enable access to DLM and DL.

↓

Set DLM and DLL      Set the divisor.

↓

LCR[7] = 0b      Disable access to DLM and DLL.  
Generation of a 16x baud rate clock is started.

↓

3. Set the FIFO.

FCR[0]      Set FIFO mode or non-FIFO mode.

FCR[3]      Select the DMA mode.

FCR[5]      Select FIFO 16- or 64-byte mode.

FCR[7:6]      Select the triggering level for the reception FIFO.

↓

4. Set the serial interface.

LCR[1:0]      Specify the data bit length.

LCR[2]      Specify the number of stop bits.

LCR[5:3]      Select parity as odd, even, stick, or none.

↓

5. Set the modem interface.

MCR[0] = 1b      Activate the DTR\_N output.

MCR[5][1]      Set flow control.

If auto flow control is not to be used, set MCR[1] = 1b to activate the RTS\_N output.

Setting for the basic operating modes is now completed.

### 39.5.2 Data Transfer

After the basic initialization, to proceed with data transfer (PIO transfer, DMA transfer) through the host bus, set IER and HCR0 to activate the interrupt/DMA function.

↓

6. Set the reception line status interrupt and the modem status interrupt.

IER [3:2] = 11b

Enabling the modem status interrupt may immediately lead to generation of this interrupt. To prevent this, read the value of the MSR register to clear it before making this setting.

#### 39.5.2.1 PIO Transfer

PIO transfer refers to transfer by interrupt or polling. In reception, processing for reception proceeds upon reception of data. In transmission, processing for transmission proceeds unless the FIFO buffer is full.

↓

- Register settings in the case of data transfer by interrupt

HCR0[6] Set auto-RTS mode.

IER[1:0] = 11b Enable interrupts for response to the transmission buffer being empty and received data being present.

#### 39.5.2.2 DMA Transfer

The settings for data transfer with the use of the DMA controller and the flow of transfer are described.

↓

- Setting the value of HW Control Register 0 (HCR0)

HCR0[6] Set auto-RTS mode.

HCR0[5:2] Set additional DMA modes.

HCR0[1:0] = 11b Enable DMA requests for transmission and reception.

The following are flowcharts for DMA transfer in DMA modes (1) to (6) listed in **Table 39.4-3**.

Figure 39.5-1 DMA Transfer Flow for Reception (in (1) Non-FIFO Mode)

Figure 39.5-2 DMA Transfer Flow for Reception (in (2) Mode 0 when the FIFO Buffer is in Use)

Figure 39.5-3 DMA Transfer Flow for Reception (a Time-out in Mode 1 when the FIFO Buffer is in Use is Included in the DMA Request Issuing Conditions)

Figure 39.5-4 DMA Transfer Flow for Reception (a Time-out in Mode 1 when the FIFO Buffer is in Use is Excluded from the DMA Request Issuing Conditions)

Figure 39.5-5 DMA Transfer Flow for Transmission (in (4) Non-FIFO Mode)

Figure 39.5-6 DMA Transfer Flow for Transmission (in (5) Mode 0)

Figure 39.5-7 DMA Transfer Flow for Transmission (in (6) Mode 1)

## 39.6 Usage Notes

### 39.6.1 Point for Caution when Changing the Register Settings

When changing the settings of the following registers, a PRESETn master reset or FIFO reset + SW reset (FCR[2], FCR[1], HCR0[7]) must be input to re-initialize them.

Target Registers: FCR[7:5], FCR[3:0], LCR[7][5:0], MCR[6:4], DLL[7:0], DLM[7:0], HCR0[6:5][3:2]

## Section 40 Pin Function Controller (PFC)

This section describes the functions of the pin function controller (PFC).

### 40.1 Functional Overview

The PFC is a control unit for external pins of the LSI, which includes the general-purpose input/output port (GPIO) function.

The following pins are for use with the ISP support package, so do not use the PFC registers related to these pins.

Pin Names:

PM0, PM1, PM2, PM3, PM4, PM5, PM6, PM7, PM15, INEXINT0, INEXINT1, INEXINT2, INEXINT3,  
CSTXD1, CSRXD1, CSSCLK1, CSCS1, CSSCLK2, CSCS2, CSTXD3, CSRXD3, CSSCLK3, CSCS3,  
CSTXD5, CSRXD5, CSSCLK5, CSCS5, I2SDA1, I2SCL1,  
P0600, P0601, P0602, P0603, P0604, P0605, P0606, P0607,  
AULRCK, AUBICK, AUDI, AUDIO, AUMCLK, AUPLLCLK,  
IM0VS, IM0HS, IM0CS, IM0TXD, IM0RXD, IM0SCLK, IM0SIG0, IM0SIG1, IM0SIG2,  
IM1VS, IM1HS, IM1CS, IM1TXD, IM1RXD, IM1SCLK, IM1SIG0, IM1SIG1, IM1SIG2,  
IMSHUT0, IMSHUT1, IMSTSIG0, IMSTSIG1,  
MTDRV0, MTDRV1, MTDRV2, MTDRV3, MTDRV4, MTDRV5, MTDRV6, MTDRV7,  
MTDCPLS0, MTDCPLS1, MTDCPLS2, MTDCPLS3,  
MTCS0, MTTXD0, MTRXD0, MTSCLK0, MTCS1, MTTXD1, MTRXD1, MTSCLK1,  
HDSCL, HDSDA, HDHPD

As this pin is intended to be used for LED control during the boot sequence, do not use the registers related to it.

Pin Name: MD8

Table 40.1-1 PFC Functions in Outline

| Category                | Function                | Description                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pin Function Controller | Pin Function Controller | <ul style="list-style-type: none"> <li>• GPIO control</li> <li>• LSI multiplexed pin switching</li> <li>• Pull-up/down control for LSI pins</li> <li>• Drive strength switching for LSI pins</li> <li>• Slew rate switching for LSI pins</li> <li>• CSRXD input pin selection</li> <li>• External interrupt signal masking control</li> <li>• External interrupt signal active sense non-inversion/inversion control</li> </ul> |

### 40.1.1 Multiplexed Pins

The multiplexed pins of this LSI pin are divided into 20 categories (PORT00 to PORT17, PORT20, and PORT21).

Note: PORT18 and PORT19 are the missing numbers.

**Table 40.1-2** lists the correspondence between the external pins and the IO buffer control functions.

**Table 40.1-3** lists the correspondence between the external pins, the multiplexed pin functions, and the GPIO functions.

For the control registers, see **Section 40.4.2.1** to **Section 40.4.2.223**.

Supplementary notes:

PF\_SEL switching: Multiplexed function switching control for the external pins

PU/PD switching: Pull-up/pull-down switching control for the external pins

DRV: Drive strength switching control for the external pins

SR: Slew rate switching control for the external pins

DI masking: Masking control for data input from the external pins

EN masking: IO buffer input/output enable control for the external pins

Table 40.1-2 External Pins, Port Assignments, and Functions of the Ports (1/5)

| External Pin | Port Assignment | External Pin Control             |                 |               |              |                    |                    |
|--------------|-----------------|----------------------------------|-----------------|---------------|--------------|--------------------|--------------------|

**Note:** “—” indicates that no multiplexed pin function is assigned and setting is prohibited.

### 40.1.2 Dedicated Pins

The dedicated pins of this LSI chip are divided into two categories (PEX0, PEX1).

**Table 40.1-4** lists the correspondence between the external pins and the IO buffer control functions.

For the control registers, see **Section 40.4.2.225** to **Section 40.4.2.226**.

Supplementary notes:

PF\_SEL switching: Multiplexed function switching control for the external pins

PU/PD switching: Pull-up/pull-down switching control for the external pins

DRV: Drive strength switching control for the external pins

SR: Slew rate switching control for the external pins

DI masking: Masking control for data input from the external pins

EN masking: IO buffer input/output enable control for the external pins

Table 40.1-4 Dedicated Pins and Port Assignments

| External Pin | Port Assignment | External Pin Control                   |                    |                  |                 |                       |                       |            |

**Note:** PEX0[11], PEX0[13], and PEX1[0] are the missing numbers because their specifications have been deleted.

**Note:** “—” indicates that these pins have no function.

## 40.2 Internal Configuration

Figure 40.2-1 shows the internal configuration of the PFC.

The PFC unit handles switching of the multiplexed pin function and control of the I/O buffer through register control by the APB slave.

Figure 40.2-1 Internal Configuration of PFC

- PFC\_APB:

This block handles register control by the APB slave interface.

It includes the following registers.

- PFC\_DI\_MON: A register block for monitoring the input values on the external pins
- GPIO: A register block for controlling the general-purpose input/output ports
- PIN\_FUNC\_CONT: A register block for controlling the following functions
  1. LSI multiplexed pin switching
  2. Pull-up/down control for the LSI pins
  3. Drive strength switching for the LSI pins
  4. Slew rate switching for the LSI pins
  5. Input/output enable masking control for the LSI pins
  6. Masking control for input data from the LSI pins
  7. CSRXD input pin selection
  8. Masking control for the external interrupt signal
  9. Non-version/inversion control for the active sense of the external interrupt signal

- PFC\_PERI:

This block controls the following.

- Invert the active sense of the active-high output enable signal output by a given unit to make the signal active-low.
- Output of the I/O buffer control signal in place of the unit that does not output the control signal
- Selection of the input signal to the CSRXD pin of CSI
- External interrupt signal masking control
- External interrupt signal active sense non-inversion/inversion control

- PFC\_CORE:

This block has the following functions.

- Multiplexed pin function switching for the external pins by the PFC\_APB output control signal (Pnn\_PFSEL)
  - Selection of the signal output to the corresponding external pin
  - Selection of the output destination of the input signal from the corresponding external pin
- Forcible disabling of the input/output enable signal of the IO buffer assigned to the multiplexed pins by the PFC\_APB output control signal (Pnn\_EN\_MSK signal) (to prevent glitches which are generated when switching the multiplexed pin function).
- Forcible masking of input data on the corresponding external pin by the PFC\_APB output control signal (Pnn\_DI\_MSK signal) (to prevent glitches which are generated when switching the multiplexed pin function).

Note: nn = 00 to 17, 20

### 40.2.1 Internal Configuration of External Interrupt Signal Active Sense Non-Inversion/Inversion Control and Masking

Non-inversion or inversion of the external interrupt can be controlled by the settings of EXTINT\_INV0 to 2 registers.

Additionally, masking of the external interrupt can be controlled by the settings of EXTINT\_MSK0 to 2 registers.

When the setting is for masking (EXTINT\_MSK[n] = 1), the output of the interrupt signal to the interrupt controller (GIC) is fixed at the low level (inactive) regardless of the setting of EXTINT\_INV0 to 2 registers and the input value on EXTINT,

**Figure 40.2-2** shows the internal configuration of non-inversion/inversion control for the active sense of the external interrupt signal.

Figure 40.2-2 Internal Configuration of External Interrupt Signal Active Sense Non-Inversion/Inversion Control

## 40.3 Pin Functions

### 40.3.1 List of Internal Pins

#### 40.3.1.1 List of Pins for PORT00 and PORT01

**Table 40.3-1** lists the internal pins for PORT00 and PORT01.

Table 40.3-1 List of Internal Pins (PORT00, PORT01) (1/2)

| Pin Name                        | I/O    | Function                                              |
|---------------------------------|--------|-------------------------------------------------------|
| PORT00 I/O Buffer (from/to PAD) |        |                                                       |
| P00_DO[13:0]                    | Output | P00 I/O buffer output signal                          |
| P00_OE_N[13:0]                  | Output | P00 I/O buffer output enable signal                   |
| P00_DI[13:0]                    | Input  | P00 I/O buffer input signal                           |
| P00_IE[13:0]                    | Output | P00 I/O buffer input enable signal                    |
| P00_DRV1[13:0]                  | Output | P00 I/O buffer drive strength switching signal 1      |
| P00_DRV2[13:0]                  | Output | P00 I/O buffer drive strength switching signal 2      |
| P00_PE_N[13:0]                  | Output | P00 I/O buffer pull-up/down enable signal             |
| P00_PSEL[13:0]                  | Output | P00 I/O buffer pull-up/down switching signal          |
| P00_SR[13:0]                    | Output | P00 I/O buffer slew rate switching signal             |
| P00_11_IE1                      | Output | P00[11] I/O buffer returned clock input enable signal |
| PORT00 Peripheral Pin Function  |        |                                                       |
| P00_PF1_DO[13:0]                | Input  | P00 multiplexed function 1 output signal              |
| P00_PF2_DO[13:0]                | Input  | P00 multiplexed function 2 output signal              |
| P00_PF1_OE_N[13:0]              | Input  | P00 multiplexed function 1 output enable signal       |
| P00_PF2_OE_N[13:0]              | Input  | P00 multiplexed function 2 output enable signal       |
| P00_PF1_DI[13:0]                | Output | P00 multiplexed function 1 input signal               |
| P00_PF2_DI[13:0]                | Output | P00 multiplexed function 2 input signal               |
| PORT01 I/O Buffer (from/to PAD) |        |                                                       |
| P01_DO[15:0]                    | Output | P01 I/O buffer output signal                          |
| P01_OE_N[15:0]                  | Output | P01 I/O buffer output enable signal                   |
| P01_DI[15:0]                    | Input  | P01 I/O buffer input signal                           |
| P01_IE[15:0]                    | Output | P01 I/O buffer input enable signal                    |
| P01_DRV1[15:0]                  | Output | P01 I/O buffer drive strength switching signal 1      |
| P01_DRV2[15:0]                  | Output | P01 I/O buffer drive strength switching signal 2      |
| P01_PE_N[15:0]                  | Output | P01 I/O buffer pull-up/down enable signal             |
| P01_PSEL[15:0]                  | Output | P01 I/O buffer pull-up/down switching signal          |
| P01_SR[15:0]                    | Output | P01 I/O buffer slew rate switching signal             |
| PORT01 Peripheral Pin Function  |        |                                                       |
| P01_PF1_DO[15:0]                | Input  | P01 multiplexed function 1 output signal              |
| P01_PF3_DO[15:0]                | Input  | P01 multiplexed function 3 output signal              |
| P01_PF5_DO[15:0]                | Input  | P01 multiplexed function 5 output signal              |
| P01_PF6_DO[15:0]                | Input  | P01 multiplexed function 6 output signal              |

| P03_PF5_DO[15:0]                | Input  | P03 multiplexed function 5 output signal         |
| P03_PF6_DO[15:0]                | Input  | P03 multiplexed function 6 output signal         |
| P03_PF7_DO[15:0]                | Input  | P03 multiplexed function 7 output signal         |
| P03_PF1_OE[15:0]                | Input  | P03 multiplexed function 1 output enable signal  |
| P03_PF2_OE_N[15:0]              | Input  | P03 multiplexed function 2 output enable signal  |
| P03_PF1_DI[15:0]                | Output | P03 multiplexed function 1 input signal          |
| P03_PF2_DI[15:0]                | Output | P03 multiplexed function 2 input signal          |
| P03_PF7_DI[15:0]                | Output | P03 multiplexed function 7 input signal          |

### 40.3.1.3 List of Pins for PORT04 and PORT05

**Table 40.3-3** lists the internal pins for PORT04 and PORT05.

Table 40.3-3 List of Internal Pins (PORT04, PORT05)

| Pin Name                        | I/O    | Function                                         |
|---------------------------------|--------|--------------------------------------------------|
| PORT04 I/O Buffer (from/to PAD) |        |                                                  |
| P04_DO[7:0]                     | Output | P04 I/O buffer output signal                     |
| P04_OE_N[7:0]                   | Output | P04 I/O buffer output enable signal              |
| P04_DI[7:0]                     | Input  | P04 I/O buffer input signal                      |
| P04_IE[7:0]                     | Output | P04 I/O buffer input enable signal               |
| P04_DRV1[7:0]                   | Output | P04 I/O buffer drive strength switching signal 1 |
| P04_DRV2[7:0]                   | Output | P04 I/O buffer drive strength switching signal 2 |
| P04_PE_N[7:0]                   | Output | P04 I/O buffer pull-up/down enable signal        |
| P04_PSEL[7:0]                   | Output | P04 I/O buffer pull-up/down switching signal     |
| P04_SR[7:0]                     | Output | P04 I/O buffer slew rate switching signal        |
| PORT04 Peripheral Pin Function  |        |                                                  |
| P04_PF1_DO[7:0]                 | Input  | P04 multiplexed function 1 output signal         |
| P04_PF4_DO[7:0]                 | Input  | P04 multiplexed function 4 output signal         |
| P04_PF1_OE[7:0]                 | Input  | P04 multiplexed function 1 output enable signal  |
| P04_PF1_DI[7:0]                 | Output | P04 multiplexed function 1 input signal          |
| PORT05 I/O Buffer (from/to PAD) |        |                                                  |
| P05_DO[3:0]                     | Output | P05 I/O buffer output signal                     |
| P05_OE_N[3:0]                   | Output | P05 I/O buffer output enable signal              |
| P05_DI[3:0]                     | Input  | P05 I/O buffer input signal                      |
| P05_IE[3:0]                     | Output | P05 I/O buffer input enable signal               |
| P05_DRV1[3:0]                   | Output | P05 I/O buffer drive strength switching signal 1 |
| P05_DRV2[3:0]                   | Output | P05 I/O buffer drive strength switching signal 2 |
| P05_PE_N[3:0]                   | Output | P05 I/O buffer pull-up/down enable signal        |
| P05_PSEL[3:0]                   | Output | P05 I/O buffer pull-up/down switching signal     |
| P05_SR[3:0]                     | Output | P05 I/O buffer slew rate switching signal        |
| PORT05 Peripheral Pin Function  |        |                                                  |
| P05_PF2_DO[3:0]                 | Input  | P05 multiplexed function 2 output signal         |
| P05_PF2_OE_N[3:0]               | Input  | P05 multiplexed function 2 output enable signal  |
| P05_PF2_DI[3:0]                 | Output | P05 multiplexed function 2 input signal          |

#### 40.3.1.4 List of Pins for PORT06 and PORT07

**Table 40.3-4** lists the internal pins for PORT06 and PORT07.

Table 40.3-4 List of Internal Pins (PORT06, PORT07)

| Pin Name                        | I/O    | Function                                         |
|---------------------------------|--------|--------------------------------------------------|
| PORT06 I/O Buffer (from/to PAD) |        |                                                  |
| P06_DO[11:0]                    | Output | P06 I/O buffer output signal                     |
| P06_OE_N[11:0]                  | Output | P06 I/O buffer output enable signal              |
| P06_DI[11:0]                    | Input  | P06 I/O buffer input signal                      |
| P06_IE[11:0]                    | Output | P06 I/O buffer input enable signal               |
| P06_DRV1[11:0]                  | Output | P06 I/O buffer drive strength switching signal 1 |
| P06_DRV2[11:0]                  | Output | P06 I/O buffer drive strength switching signal 2 |
| P06_PE_N[11:0]                  | Output | P06 I/O buffer pull-up/down enable signal        |
| P06_PSEL[11:0]                  | Output | P06 I/O buffer pull-up/down switching signal     |
| P06_SR[11:0]                    | Output | P06 I/O buffer slew rate switching signal        |
| PORT06 Peripheral Pin Function  |        |                                                  |
| P06_PF5_DO[11:0]                | Input  | P06 multiplexed function 5 output signal         |
| P06_PF6_DO[11:0]                | Input  | P06 multiplexed function 6 output signal         |
| P06_PF7_DO[11:0]                | Input  | P06 multiplexed function 7 output signal         |
| P06_PF7_DI[11:0]                | Output | P06 multiplexed function 7 input signal          |
| PORT07 I/O Buffer (from/to PAD) |        |                                                  |
| P07_DO[5:0]                     | Output | P07 I/O buffer output signal                     |
| P07_OE_N[5:0]                   | Output | P07 I/O buffer output enable signal              |
| P07_DI[5:0]                     | Input  | P07 I/O buffer input signal                      |
| P07_IE[5:0]                     | Output | P07 I/O buffer input enable signal               |
| P07_DRV1[5:0]                   | Output | P07 I/O buffer drive strength switching signal 1 |
| P07_DRV2[5:0]                   | Output | P07 I/O buffer drive strength switching signal 2 |
| P07_PE_N[5:0]                   | Output | P07 I/O buffer pull-up/down enable signal        |
| P07_PSEL[5:0]                   | Output | P07 I/O buffer pull-up/down switching signal     |
| P07_SR[5:0]                     | Output | P07 I/O buffer slew rate switching signal        |
| PORT07 Peripheral Pin Function  |        |                                                  |
| P07_PF1_DO[5:0]                 | Input  | P07 multiplexed function 1 output signal         |
| P07_PF1_DI[5:0]                 | Output | P07 multiplexed function 1 input signal          |

### 40.3.1.5 List of Pins for PORT08 and PORT09

**Table 40.3-5** lists the internal pins for PORT08 and PORT09.

Table 40.3-5 List of Internal Pins (PORT08, PORT09)

| Pin Name                        | I/O    | Function                                             |
|---------------------------------|--------|------------------------------------------------------|
| PORT08 I/O Buffer (from/to PAD) |        |                                                      |
| P08_DO[7:0]                     | Output | P08 I/O buffer output signal                         |
| P08_OE_N[7:0]                   | Output | P08 I/O buffer output enable signal                  |
| P08_DI[7:0]                     | Input  | P08 I/O buffer input signal                          |
| P08_IE[7:0]                     | Output | P08 I/O buffer input enable signal                   |
| P08_DRV1[7:0]                   | Output | P08 I/O buffer drive strength switching signal 1     |
| P08_DRV2[7:0]                   | Output | P08 I/O buffer drive strength switching signal 2     |
| P08_PE_N[7:0]                   | Output | P08 I/O buffer pull-up/down enable signal            |
| P08_PSEL[7:0]                   | Output | P08 I/O buffer pull-up/down switching signal         |
| P08_SR[7:0]                     | Output | P08 I/O buffer slew rate switching signal            |
| P08_01_IE1                      | Output | P08[1] I/O buffer returned clock input enable signal |
| PORT08 Peripheral Pin Function  |        |                                                      |
| P08_PF1_DO[7:0]                 | Input  | P08 multiplexed function 1 output signal             |
| P08_PF2_DO[7:0]                 | Input  | P08 multiplexed function 2 output signal             |
| P08_PF1_OE_N[7:0]               | Input  | P08 multiplexed function 1 output enable signal      |
| P08_PF1_DI[7:0]                 | Output | P08 multiplexed function 1 input signal              |
| PORT09 I/O Buffer (from/to PAD) |        |                                                      |
| P09_DO[7:0]                     | Output | P09 I/O buffer output signal                         |
| P09_OE_N[7:0]                   | Output | P09 I/O buffer output enable signal                  |
| P09_DI[7:0]                     | Input  | P09 I/O buffer input signal                          |
| P09_IE[7:0]                     | Output | P09 I/O buffer input enable signal                   |
| P09_DRV1[7:0]                   | Output | P09 I/O buffer drive strength switching signal 1     |
| P09_DRV2[7:0]                   | Output | P09 I/O buffer drive strength switching signal 2     |
| P09_PE_N[7:0]                   | Output | P09 I/O buffer pull-up/down enable signal            |
| P09_PSEL[7:0]                   | Output | P09 I/O buffer pull-up/down switching signal         |
| P09_SR[7:0]                     | Output | P09 I/O buffer slew rate switching signal            |
| P09_01_IE1                      | Output | P09[1] I/O buffer returned clock input enable signal |
| PORT09 Peripheral Pin Function  |        |                                                      |
| P09_PF1_DO[7:0]                 | Input  | P09 multiplexed function 1 output signal             |
| P09_PF1_OE_N[7:0]               | Input  | P09 multiplexed function 1 output enable signal      |
| P09_PF1_DI[7:0]                 | Output | P09 multiplexed function 1 input signal              |
| P09_PF2_DI[7:0]                 | Output | P09 multiplexed function 2 input signal              |

### 40.3.1.6 List of Pins for PORT10 and PORT11

**Table 40.3-6** lists the internal pins for PORT10 and PORT11.

Table 40.3-6 List of Internal Pins (PORT10, PORT11)

| Pin Name                        | I/O    | Function                                         |
|---------------------------------|--------|--------------------------------------------------|
| PORT10 I/O Buffer (from/to PAD) |        |                                                  |
| P10_DO[8:0]                     | Output | P10 I/O buffer output signal                     |
| P10_OE_N[8:0]                   | Output | P10 I/O buffer output enable signal              |
| P10_DI[8:0]                     | Input  | P10 I/O buffer input signal                      |
| P10_IE[8:0]                     | Output | P10 I/O buffer input enable signal               |
| P10_DRV1[8:0]                   | Output | P10 I/O buffer drive strength switching signal 1 |
| P10_DRV2[8:0]                   | Output | P10 I/O buffer drive strength switching signal 2 |
| P10_PE_N[8:0]                   | Output | P10 I/O buffer pull-up/down enable signal        |
| P10_PSEL[8:0]                   | Output | P10 I/O buffer pull-up/down switching signal     |
| P10_SR[8:0]                     | Output | P10 I/O buffer slew rate switching signal        |
| PORT10 Peripheral Pin Function  |        |                                                  |
| P10_PF1_DO[8:0]                 | Input  | P10 multiplexed function 1 output signal         |
| P10_PF1_OE[8:0]                 | Input  | P10 multiplexed function 1 output enable signal  |
| P10_PF1_IE[8:0]                 | Input  | P10 multiplexed function 1 input enable signal   |
| P10_PF1_DI[8:0]                 | Output | P10 multiplexed function 1 input signal          |
| P10_PF2_DI[8:0]                 | Output | P10 multiplexed function 2 input signal          |
| PORT11 I/O Buffer (from/to PAD) |        |                                                  |
| P11_DO[8:0]                     | Output | P11 I/O buffer output signal                     |

| P11_PF2_DI[8:0]                 | Output | P11 multiplexed function 2 input signal          |

### 40.3.1.7 List of Pins for PORT12 and PORT13

**Table 40.3-7** lists the internal pins for PORT12 and PORT13.

Table 40.3-7 List of Internal Pins (PORT12, PORT13)

| Pin Name                        | I/O    | Function                                         |
|---------------------------------|--------|--------------------------------------------------|
| PORT12 I/O Buffer (from/to PAD) |        |                                                  |
| P12_DO[3:0]                     | Output | P12 I/O buffer output signal                     |
| P12_OE_N[3:0]                   | Output | P12 I/O buffer output enable signal              |
| P12_DI[3:0]                     | Input  | P12 I/O buffer input signal                      |
| P12_IE[3:0]                     | Output | P12 I/O buffer input enable signal               |
| P12_DRV1[3:0]                   | Output | P12 I/O buffer drive strength switching signal 1 |
| P12_DRV2[3:0]                   | Output | P12 I/O buffer drive strength switching signal 2 |
| P12_PE_N[3:0]                   | Output | P12 I/O buffer pull-up/down enable signal        |
| P12_PSEL[3:0]                   | Output | P12 I/O buffer pull-up/down switching signal     |
| P12_SR[3:0]                     | Output | P12 I/O buffer slew rate switching signal        |
| PORT12 Peripheral Pin Function  |        |                                                  |
| P12_PF1_DO[3:0]                 | Input  | P12 multiplexed function 1 output signal         |
| P12_PF2_DI[3:0]                 | Output | P12 multiplexed function 2 input signal          |
| PORT13 I/O Buffer (from/to PAD) |        |                                                  |
| P13_DO[11:0]                    | Output | P13 I/O buffer output signal                     |
| P13_OE_N[11:0]                  | Output | P13 I/O buffer output enable signal              |
| P13_DI[11:0]                    | Input  | P13 I/O buffer input signal                      |
| P13_IE[11:0]                    | Output | P13 I/O buffer input enable signal               |
| P13_DRV1[11:0]                  | Output | P13 I/O buffer drive strength switching signal 1 |
| P13_DRV2[11:0]                  | Output | P13 I/O buffer drive strength switching signal 2 |
| P13_PE_N[11:0]                  | Output | P13 I/O buffer pull-up/down enable signal        |
| P13_PSEL[11:0]                  | Output | P13 I/O buffer pull-up/down switching signal     |
| P13_SR[11:0]                    | Output | P13 I/O buffer slew rate switching signal        |
| PORT13 Peripheral Pin Function  |        |                                                  |
| P13_PF3_DO[11:0]                | Input  | P13 multiplexed function 3 output signal         |
| P13_PF4_DO[11:0]                | Input  | P13 multiplexed function 4 output signal         |
| P13_PF2_DI[11:0]                | Output | P13 multiplexed function 2 input signal          |
| P13_PF3_DI[11:0]                | Output | P13 multiplexed function 3 input signal          |

### 40.3.1.8 List of Pins for PORT14 and PORT15

**Table 40.3-8** lists the internal pins for PORT14 and PORT15.

Table 40.3-8 List of Internal Pins (PORT14, PORT15)

| Pin Name                        | I/O    | Function                                         |
|---------------------------------|--------|--------------------------------------------------|
| PORT14 I/O Buffer (from/to PAD) |        |                                                  |
| P14_DO[7:0]                     | Output | P14 I/O buffer output signal                     |
| P14_OE_N[7:0]                   | Output | P14 I/O buffer output enable signal              |
| P14_DI[7:0]                     | Input  | P14 I/O buffer input signal                      |
| P14_IE[7:0]                     | Output | P14 I/O buffer input enable signal               |
| P14_DRV1[7:0]                   | Output | P14 I/O buffer drive strength switching signal 1 |
| P14_DRV2[7:0]                   | Output | P14 I/O buffer drive strength switching signal 2 |
| P14_PE_N[7:0]                   | Output | P14 I/O buffer pull-up/down enable signal        |
| P14_PSEL[7:0]                   | Output | P14 I/O buffer pull-up/down switching signal     |
| P14_SR[7:0]                     | Output | P14 I/O buffer slew rate switching signal        |
| PORT14 Peripheral Pin Function  |        |                                                  |
| P14_PF3_DO[7:0]                 | Input  | P14 multiplexed function 3 output signal         |
| P14_PF4_DO[7:0]                 | Input  | P14 multiplexed function 4 output signal         |
| P14_PF2_DI[7:0]                 | Output | P14 multiplexed function 2 input signal          |
| P14_PF3_DI[7:0]                 | Output | P14 multiplexed function 3 input signal          |
| PORT15 I/O Buffer (from/to PAD) |        |                                                  |
| P15_DO[15:0]                    | Output | P15 I/O buffer output signal                     |
| P15_OE_N[15:0]                  | Output | P15 I/O buffer output enable signal              |
| P15_DI[15:0]                    | Input  | P15 I/O buffer input signal                      |
| P15_IE[15:0]                    | Output | P15 I/O buffer input enable signal               |
| P15_DRV1[15:0]                  | Output | P15 I/O buffer drive strength switching signal 1 |
| P15_DRV2[15:0]                  | Output | P15 I/O buffer drive strength switching signal 2 |
| P15_PE_N[15:0]                  | Output | P15 I/O buffer pull-up/down enable signal        |
| P15_PSEL[15:0]                  | Output | P15 I/O buffer pull-up/down switching signal     |
| P15_SR[15:0]                    | Output | P15 I/O buffer slew rate switching signal        |
| PORT15 Peripheral Pin Function  |        |                                                  |
| P15_PF1_DO[15:0]                | Input  | P15 multiplexed function 1 output signal         |
| P15_PF2_DO[15:0]                | Input  | P15 multiplexed function 2 output signal         |
| P15_PF4_DO[15:0]                | Input  | P15 multiplexed function 4 output signal         |
| P15_PF5_DO[15:0]                | Input  | P15 multiplexed function 5 output signal         |
| P15_PF6_DO[15:0]                | Input  | P15 multiplexed function 6 output signal         |
| P15_PF7_DO[15:0]                | Input  | P15 multiplexed function 7 output signal         |
| P15_PF1_DI[15:0]                | Output | P15 multiplexed function 1 input signal          |

### 40.3.1.9 List of Pins for PORT16 and PORT17

**Table 40.3-9** lists the internal pins for PORT16 and PORT17.

Table 40.3-9 List of Internal Pins (PORT16, PORT17)

| Pin Name                        | I/O    | Function                                         |
|---------------------------------|--------|--------------------------------------------------|
| PORT16 I/O Buffer (from/to PAD) |        |                                                  |
| P16_DO[13:0]                    | Output | P16 I/O buffer output signal                     |
| P16_OE_N[13:0]                  | Output | P16 I/O buffer output enable signal              |
| P16_DI[13:0]                    | Input  | P16 I/O buffer input signal                      |
| P16_IE[13:0]                    | Output | P16 I/O buffer input enable signal               |
| P16_DRV1[13:0]                  | Output | P16 I/O buffer drive strength switching signal 1 |
| P16_DRV2[13:0]                  | Output | P16 I/O buffer drive strength switching signal 2 |
| P16_PE_N[13:0]                  | Output | P16 I/O buffer pull-up/down enable signal        |
| P16_PSEL[13:0]                  | Output | P16 I/O buffer pull-up/down switching signal     |
| P16_SR[13:0]                    | Output | P16 I/O buffer slew rate switching signal        |
| PORT16 Peripheral Pin Function  |        |                                                  |
| P16_PF1_DO[13:0]                | Input  | P16 multiplexed function 1 output signal         |
| P16_PF2_DO[13:0]                | Input  | P16 multiplexed function 2 output signal         |
| P16_PF3_DO[13:0]                | Input  | P16 multiplexed function 3 output signal         |
| P16_PF4_DO[13:0]                | Input  | P16 multiplexed function 4 output signal         |
| P16_PF5_DO[13:0]                | Input  | P16 multiplexed function 5 output signal         |
| P16_PF6_DO[13:0]                | Input  | P16 multiplexed function 6 output signal         |
| P16_PF7_DO[13:0]                | Input  | P16 multiplexed function 7 output signal         |
| P16_PF1_OE[13:0]                | Input  | P16 multiplexed function 1 output enable signal  |
| P16_PF2_OE[13:0]                | Input  | P16 multiplexed function 2 output enable signal  |
| P16_PF2_IE[13:0]                | Input  | P16 multiplexed function 2 input enable signal   |
| P16_PF1_DI[13:0]                | Output | P16 multiplexed function 1 input signal          |
| P16_PF2_DI[13:0]                | Output | P16 multiplexed function 2 input signal          |
| PORT17 I/O Buffer (from/to PAD) |        |                                                  |
| P17_DO                          | Output | P17 I/O buffer output signal                     |
| P17_OE_N                        | Output | P17 I/O buffer output enable signal              |
| P17_DI                          | Input  | P17 I/O buffer input signal                      |
| P17_IE                          | Output | P17 I/O buffer input enable signal               |
| P17_DRV1                        | Output | P17 I/O buffer drive strength switching signal 1 |
| P17_DRV2                        | Output | P17 I/O buffer drive strength switching signal 2 |
| P17_PE_N                        | Output | P17 I/O buffer pull-up/down enable signal        |
| P17_PSEL                        | Output | P17 I/O buffer pull-up/down switching signal     |
| P17_SR                          | Output | P17 I/O buffer slew rate switching signal        |
| PORT17 Peripheral Pin Function  |        |                                                  |
| P17_PF1_DO                      | Input  | P17 multiplexed function 1 output signal         |
| P17_PF2_DO                      | Input  | P17 multiplexed function 2 output signal         |
| P17_PF5_DO                      | Input  | P17 multiplexed function 5 output signal         |
| P17_PF6_DO                      | Input  | P17 multiplexed function 6 output signal         |
| P17_PF7_DO                      | Input  | P17 multiplexed function 7 output signal         |

#### 40.3.1.10 List of Pins for PORT20 and PORT21

**Table 40.3-10** lists the internal pins for PORT20 and PORT21.

Table 40.3-10 List of Internal Pins (PORT20, PORT21)

| Pin Name                        | I/O    | Function                                         |
|---------------------------------|--------|--------------------------------------------------|
| PORT20 I/O Buffer (from/to PAD) |        |                                                  |
| P20_DO[2:0]                     | Output | P20 I/O buffer output signal                     |
| P20_OE_N[2:0]                   | Output | P20 I/O buffer output enable signal              |
| P20_DI[2:0]                     | Input  | P20 I/O buffer input signal                      |
| P20_IE[2:0]                     | Output | P20 I/O buffer input enable signal               |
| P20_DRV1[2:0]                   | Output | P20 I/O buffer drive strength switching signal 1 |
| P20_DRV2[2:0]                   | Output | P20 I/O buffer drive strength switching signal 2 |
| P20_PE_N[2:0]                   | Output | P20 I/O buffer pull-up/down enable signal        |
| P20_PSEL[2:0]                   | Output | P20 I/O buffer pull-up/down switching signal     |
| PORT20 Peripheral Pin Function  |        |                                                  |

#### 40.3.1.11 List of Dedicated Pin Control Pins

**Table 40.3-11** lists the internal pins which control the dedicated pins.

Table 40.3-11 List of Internal Pins (Dedicated Pin Control)

| Pin Name                                | I/O    | Function                                                 |
|-----------------------------------------|--------|----------------------------------------------------------|
| Exclusive PORT0 I/O Buffer (to PAD)     |        |                                                          |
| PEX0_OE_N[5:0]                          | Output | Dedicated 0 I/O buffer output enable signal [5:0]        |
| PEX0_OE_N[6]                            | Output | Dedicated 0 I/O buffer output enable signal [6]          |
| PEX0_OE_N[15:7]                         | Output | Dedicated 0 I/O buffer output enable signal [15:7]       |
| PEX0_IE[15:0]                           | Output | Dedicated 0 I/O buffer input enable signal               |
| PEX0_DRV1[15:0]                         | Output | Dedicated 0 I/O buffer drive strength switching signal 1 |
| PEX0_DRV2[15:0]                         | Output | Dedicated 0 I/O buffer drive strength switching signal 2 |
| PEX0_PE_N[15:0]                         | Output | Dedicated 0 I/O buffer pull-up/down enable signal        |
| PEX0_PSEL[15:0]                         | Output | Dedicated 0 I/O buffer pull-up/down switching signal     |
| PEX0_SR[15:0]                           | Output | Dedicated 0 I/O buffer slew rate switching signal        |
| Exclusive PORT0 Peripheral Pin Function |        |                                                          |
| PEX0_06_OE                              | Input  | Dedicated 0 bit 6 I/O buffer output enable signal        |
| Exclusive PORT1 I/O Buffer (to PAD)     |        |                                                          |
| PEX1_OE_N[9:1]                          | Output | Dedicated 1 I/O buffer output enable signal              |
| PEX1_IE[9:1]                            | Output | Dedicated 1 I/O buffer input enable signal               |
| PEX1_DRV1[9:1]                          | Output | Dedicated 1 I/O buffer drive strength switching signal 1 |
| PEX1_DRV2[9:1]                          | Output | Dedicated 1 I/O buffer drive strength switching signal 2 |
| PEX1_PE_N[9:1]                          | Output | Dedicated 1 I/O buffer pull-up/down enable signal        |
| PEX1_PSEL[9:1]                          | Output | Dedicated 1 I/O buffer pull-up/down switching signal     |
| PEX1_SR[8:1]* <sup>1</sup>              | Output | Dedicated 1 I/O buffer slew rate switching signal        |

Note 1. The external pin (RSTN) corresponding to PEX1[9] has no slew rate switching function, so the PEX1\_SR[9] pin is not also present.

The following describes the internal pin functions of the PFC unit.

### 40.3.2 PORT00 to PORT21 I/O Buffer (from/to PAD) Control Signal

Pnn\_DO[15:0]: PORTnn I/O buffer output signal

Pnn\_OE\_N[15:0]: PORTnn I/O buffer output enable signal

Pnn\_OE\_N[m] = 0: Enable output

Pnn\_OE\_N[m] = 1: Disable output

Pnn\_DI[15:0]: PORTnn I/O buffer input signal

Pnn\_IE[15:0]: PORTnn I/O buffer input enable signal

Pnn\_IE[m] = 0: Disable input

Pnn\_IE[m]=1: Enable input

Note: nn = 00 to 17, 20 to 21

m = 0 to 15

Pnn\_DRV1[15:0]/ Pnn\_DRV2[15:0]: PORTnn I/O buffer drive strength switching signal

The drive strength is switched as listed in the table below.

Table 40.3-12 I/O Buffer Drive Strength Switching

| DRV2 | DRV1 | Drive Strength |
|------|------|----------------|
| 0    | 0    | X1             |
| 0    | 1    | X2             |
| 1    | 0    | X4             |
| 1    | 1    | X6             |

Pnn\_PE\_N[15:0]/ Pnn\_PSEL[15:0]: PORTnn I/O buffer pull-up/down control signal

The pull-up/down is switched as listed in the table below

Table 40.3-13 I/O Buffer Pull-Up/Down Control

| PE_N | PSEL | Pull-Up/Down    |
|------|------|-----------------|
| 1    | x    | No pull-up/down |
| 0    | 0    | Pull-down       |
| 0    | 1    | Pull-up         |

Pnn\_SR[15:0]: PORTnn I/O buffer slew rate switching signal

Pnn\_SR[m] = 0: Fast slew

Pnn\_SR[m] = 1: Slow slew

Note: x: Don't care

nn = 00 to 17, 20 to 21

m = 0 to 15

The IO buffer for the eternal pins NACLE, SD0CLK, and SD1FCLK has functionality for returning the output clock to the inside before the IO buffer. The returned clock is used to ease timing adjustment for the external interfaces of eMMC, SDI0, and SDI1.

The PFC controls enable for the returned clock by using the following signals.

**P00\_11\_IE1:** NACLE pin (MMCLK) I/O buffer returned clock (TDOUT) input enable signal

1 is output when the multiplexed function for bit 11 of PORT00 is MMCLK and the setting of the enable masking register (P00\_EN\_MSK) (described later) is for removing masking; otherwise, 0 is output.

**P08\_01\_IE1:** SD0CLK pin I/O buffer returned clock (TDOUT) input enable signal

1 is output when the multiplexed function for bit 1 of PORT08 is SD0CLK and the setting of the enable masking register (P08\_EN\_MSK) (described later) is for removing masking; otherwise, 0 is output.

**P09\_01\_IE1:** SD1FCLK pin I/O buffer returned clock (TDOUT) input enable signal

1 is output when the multiplexed function for bit 1 of PORT09 is SD1FCLK and the setting of the enable masking register (P09\_EN\_MSK) (described later) is for removing masking; otherwise, 0 is output.

Pnn\_mm\_IE1 = 0: Disable the returned clock (TDOUT) input

Pnn\_mm\_IE1 = 1: Enable the returned clock (TDOUT) input

Note: {nn, mm} = {00, 11}, {08, 01}, {09, 01}

Figure 40.3-1 Schematic Block Diagram of the Returned Clock (TDOUT)

### 40.3.3 PORT00 to PORT20 Peripheral Pin Function Signals

Pnn\_PFx\_DO: Data output signal from the internal unit assigned to PORTnn multiplexed function x

Pnn\_PFx\_OE\_N: Internal unit output enable signal assigned to PORTnn multiplexed function x  
(active low)

Pnn\_PFx\_OE: Internal unit output enable signal assigned to PORTnn multiplexed function x  
(active high)

Pnn\_PFx\_IE: Internal unit input enable signal assigned to PORTnn multiplexed function x

Pnn\_PFx\_DI: Data input signal to the internal unit assigned to PORTnn multiplexed function x

Note: nn = 00 to 17, 20

x = 1 to 7

#### NOTE

The Pnn\_PFx\_DI pin for which the multiplexed function is not selected has the same value as the initial value

For the initial values of the pins, see **Section 40.4.1, List of Registers**.

## 40.4 Register Descriptions

The following lists the registers of the PFC unit.

For the register base address (<PFC\_S0\_base>), see the section of Address Map.

### 40.4.1 List of Registers

#### 40.4.1.1 List of Registers for PORT00 and PORT01

The table below lists the PFC registers for PORT00 and PORT01.

Table 40.4-1 List of PFC Registers (PORT00, PORT01) (1/2)

| Offset Address                                  | Register Name                             | Abbreviation    | Initial Value | Access Unit (bits) |
|-------------------------------------------------|-------------------------------------------|-----------------|---------------|--------------------|
| PORT00 GPIO Registers 000h-00Ch                 |                                           |                 |               |                    |
| 000h                                            | PORT00 GPIO output value control register | PFC_P00_GPIO_DO | 0000_0000h    | 32                 |
| 004h                                            | PORT00 GPIO output control register       | PFC_P00_GPIO_OE | 0000_0000h    | 32                 |
| 008h                                            | PORT00 GPIO input control register        | PFC_P00_GPIO_IE | 0000_0000h    | 32                 |
| 00Ch                                            | Reserved                                  | —               | —             | —                  |
| PORT00 Pin Function Control Registers 010h-03Ch |                                           |                 |               |                    |
| 010h                                            | PORT00 function select register 0         | PFC_P00_PFSEL0  | 0000_0000h    | 32                 |
| 014h                                            | PORT00 function select register 1         | PFC_P00_PFSEL1  | 0000_0000h    | 32                 |
| 018h                                            | PORT00 function select register 2         | PFC_P00_PFSEL2  | 0000_0000h    | 32                 |
| 01Ch                                            | PORT00 function select register 3         | PFC_P00_PFSEL3  | 0000_0000h    | 32                 |
| 020h                                            | PORT00 input value monitor register       | PFC_P00_DI_MON  | —             | 32                 |
| 024h                                            | PORT00 pull-up/down control register      | PFC_P00_PUPD    | 0556_5555h    | 32                 |
| 028h                                            | PORT00 drive strength control register    | PFC_P00_DRV     | 0555_5555h    | 32                 |
| 02Ch                                            | PORT00 slew-rate control register         | PFC_P00_SR      | 0000_3FFFh    | 32                 |
| 030h                                            | PORT00 input data mask register           | PFC_P00_DI_MSK  | 0000_3FFFh    | 32                 |
| 034h                                            | PORT00 input/output enable mask register  | PFC_P00_EN_MSK  | 0000_3FFFh    | 32                 |

#### 40.4.1.10 List of Registers for PORT20 and PORT21

The table below lists the PFC registers for PORT20 and PORT21.

Table 40.4-10 List of PFC Registers (PORT20, PORT21)

| Offset Address                                  | Register Name                             | Abbreviation    | Initial Value | Access Unit (bits) |
|-------------------------------------------------|-------------------------------------------|-----------------|---------------|--------------------|
| PORT20 GPIO Registers 500h-50Ch                 |                                           |                 |               |                    |
| 500h                                            | PORT20 GPIO output value control register | PFC_P20_GPIO_DO | 0000_0000h    | 32                 |
| 504h                                            | PORT20 GPIO output control register       | PFC_P20_GPIO_OE | 0000_0000h    | 32                 |
| 508h                                            | PORT20 GPIO input control register        | PFC_P20_GPIO_IE | 0000_0000h    | 32                 |
| 50Ch                                            | Reserved                                  | —               | —             | —                  |
| PORT20 Pin Function Control Registers 510h-53Ch |                                           |                 |               |                    |
| 510h                                            | PORT20 function select register 0         | PFC_P20_PFSEL0  | 0000_0000h    | 32                 |
| 514h-51Ch                                       | Reserved                                  | —               | —             | —                  |
| 520h                                            | PORT20 input value monitor register       | PFC_P20_DI_MON  | —             | 32                 |
| 524h                                            | Reserved                                  | —               | —             | —                  |
| 528h                                            | PORT20 drive strength control register    | PFC_P20_DRV     | 0000_0000h    | 32                 |
| 52Ch                                            | Reserved                                  | —               | —             | —                  |
| 530h                                            | PORT20 input data mask register           | PFC_P20_DI_MSK  | 0000_0007h    | 32                 |
| 534h                                            | PORT20 input/output enable mask register  | PFC_P20_EN_MSK  | 0000_0007h    | 32                 |

## 40.4.2 Register Descriptions

The function description of each register is given below.

### 40.4.2.1 PORT00 GPIO Output Value Control Register (PFC\_P00\_GPIO\_DO)

This register controls the output value of GPIO PORT00.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 0000h

**Initial Value:** 0000\_0000h

|               |    |    |              |      |      |      |      |      |      |      |      |      |      |      |      |      |
|---------------|----|----|--------------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| Bit           | 31 | 30 | 29           | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |

Table 40.4-12 PFC\_P00\_GPIO\_DO Register Contents

| Bit Position | Bit Name     | Description                                                                                      |
|--------------|--------------|--------------------------------------------------------------------------------------------------|
| 31, 30       | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                        |
| 29 to 16     | DO_WE[13:00] | Enables write to DO[13:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable  |
| 15, 14       | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                        |
| 13 to 0      | DO[13:00]    | Set the GPIO PORT00 bit[13:00] value.<br>0b: Output the low level.<br>1b: Output the high level. |

40.4.2.2 PORT00 GPIO Output Control Register (PFC\_P00\_GPIO\_OE)

This register controls whether GPIO PORT00 output is enabled or disabled.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0004h  
Initial Value: 0000\_0000h

Table 40.4-13 PFC\_P00\_GPIO\_OE Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31, 30       | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 29 to 16     | OE_WE[13:00] | Enables write to OE[13:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15, 14       | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 13 to 0      | OE[13:00]    | Control the output of GPIO PORT00 bit[13:00].<br>0b: Disable output.<br>1b: Enable output.      |

40.4.2.3 PORT00 GPIO Input Control Register (PFC\_P00\_GPIO\_IE)

This register controls whether GPIO PORT00 input is enabled or disabled.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0008h  
Initial Value: 0000\_0000h

Table 40.4-14 PFC\_P00\_GPIO\_IE Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31, 30       | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 29 to 16     | IE_WE[13:00] | Enables write to IE[13:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15, 14       | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 13 to 0      | IE[13:00]    | Control the input of GPIO PORT0 pin bit[13:00].<br>0b: Disable input.<br>1b: Enable input.      |

#### 40.4.2.4 PORT00 Function Select Register 0 (PFC\_P00\_PFSEL0)

This register controls function selection of the multi-purpose pin in PORT00.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 0010h

**Initial Value:** 0000\_0000h

**Remarks:** —: Setting prohibited

#### 40.4.2.6 PORT00 Function Select Register 2 (PFC\_P00\_PFSEL2)

This register controls function selection of the multi-purpose pin in PORT00.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 0018h

**Initial Value:** 0000\_0000h

**Remarks:** —: Setting prohibited

40.4.2.8 PORT00 Input Value Monitor Register (PFC\_P00\_DI\_MON)

This register is a read-only register that monitors the input value of the PORT00 input pin (P00\_DI).

Writing is ignored.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0020h  
Initial Value: 0000\_xxxxh

|               |    |    |           |    |    |    |    |    |    |    |    |    |    |    |    |    |

40.4.2.11 PORT00 Slew-rate Control Register (PFC\_P00\_SR)

This register controls the slew-rate of the PORT00 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 002Ch  
Initial Value: 0000\_3FFFh

Table 40.4-26 PFC\_P00\_SR Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31, 30       | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |

| 15, 14       | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 13 to 0      | SR[13:00]    | Set the PORT00 pin bit[13:00] SR value.<br>0b: Fast slew<br>1b: Slow slew                       |

40.4.2.12 PORT00 Input Data Mask Register (PFC\_P00\_DI\_MSK)

This register controls masking of input data of the PORT00 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0030h  
Initial Value: 0000\_3FFFh

Table 40.4-27 PFC\_P00\_DI\_MSK Register Contents

| Bit Position | Bit Name         | Description                                                                                                                   |
|--------------|------------------|-------------------------------------------------------------------------------------------------------------------------------|
| 31, 30       | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                                     |
| 29 to 16     | DI_MSK_WE[13:00] | Enables write to DI_MSK[13:00]. (n=00 to 13)<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable              |
| 15, 14       | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                                     |
| 13 to 0      | DI_MSK[13:00]    | Set the PORT00 DI_MSK pin value bit[13:00]. (n=00 to 13)<br>0b: Remove masking of the input data.<br>1b: Mask the input data. |

40.4.2.13 PORT00 Input/Output Enable Mask Register (PFC\_P00\_EN\_MSK)

This register controls masking of input/output enable for the PORT00 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0034h  
Initial Value: 0000\_3FFFh

Table 40.4-28 PFC\_P00\_EN\_MSK Register Contents

| Bit Position | Bit Name          | Description                                                                                                                        |
|--------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 31, 30       | —                 | Reserved. These bits are read as 0b. The write value should always be 0b.                                                          |
| 29 to 16     | EN_MSK_WE [13:00] | Enables write to EN_MSK[13:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable                                |
| 15, 14       | —                 | Reserved. These bits are read as 0b. The write value should always be 0b.                                                          |
| 13 to 0      | EN_MSK[13:00]     | Set the PORT00 EN_MSK pin bit[13:00] value.<br>0b: Remove masking of the input/output enable.<br>1b: Mask the input/output enable. |

40.4.2.14 PORT01 GPIO Output Value Control Register (PFC\_P01\_GPIO\_DO)

This register controls the output value of PORT01 GPIO.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0040h  
Initial Value: 0000\_0000h

Table 40.4-29 PFC\_P01\_GPIO\_DO Register Contents

| Bit Position | Bit Name     | Description                                                                                      |
|--------------|--------------|--------------------------------------------------------------------------------------------------|
| 31 to 16     | DO_WE[15:00] | Enables write to DO[15:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable  |
| 15 to 0      | DO[15:00]    | Set the GPIO PORT01 bit[15:00] value.<br>0b: Output the low level.<br>1b: Output the high level. |

40.4.2.15 PORT01 GPIO Output Control Register (PFC\_P01\_GPIO\_OE)

This register controls whether GPIO PORT01 output is enabled or disabled.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0044h  
Initial Value: 0000\_0000h

Table 40.4-30 PFC\_P01\_GPIO\_OE Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 16     | OE_WE[15:00] | Enables write to OE[15:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 0      | OE[15:00]    | Control the output of GPIO PORT01 bit[15:00].<br>0b: Disable output.<br>1b: Enable output.      |

40.4.2.16 PORT01 GPIO Input Control Register (PFC\_P01\_GPIO\_IE)

This register controls whether GPIO PORT01 input is enabled or disabled.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0048h  
Initial Value: 0000\_0000h

Table 40.4-31 PFC\_P01\_GPIO\_IE Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 16     | IE_WE[15:00] | Enables write to IE[15:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 0      | IE[15:00]    | Control the input of GPIO PORT01 pin bit[15:00].<br>0b: Disable input.<br>1b: Enable input.     |

#### 40.4.2.17 PORT01 Function Select Register 0 (PFC\_P01\_PFSEL0)

This register controls function selection of the multi-purpose pin in PORT01.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 0050h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30      | 29   | 28   | 27 | 26      | 25   | 24   | 23 | 22      | 21   | 20   | 19 | 18      | 17   | 16   |

**Remarks:** —: Setting prohibited

#### 40.4.2.19 PORT01 Function Select Register 2 (PFC\_P01\_PFSEL2)

This register controls function selection of the multi-purpose pin in PORT01.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 0058h

**Initial Value:** 0000\_0000h

40.4.2.21 PORT01 Input Value Monitor Register (PFC\_P01\_DI\_MON)

This register is a read-only register that monitors the input value of the PORT01 input pin (P01\_DI).

Writing is ignored.

Immediately after reset, this register becomes 0000\_0000h.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0060h  
Initial Value: 0000\_xxxxh

40.4.2.23 PORT01 Drive Strength Control Register (PFC\_P01\_DRV)

This register controls the drive strength of the PORT01 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0068h  
Initial Value: 5555\_5555h

|               |       |    |       |    |       |    |       |    |       |    |       |    |       |    |       |    |

|--------------|------------|----------------------------------------------------------------------------------------------------------|
| 31 to 0      | DRV[15:00] | Control the PORT01 pin bit[15:00] I/O buffer drive strength.<br>00b: X1<br>01b: X2<br>10b: X4<br>11b: X6 |

40.4.2.24 PORT01 Slew-rate Control Register (PFC\_P01\_SR)

This register controls the slew-rate of the PORT01 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 006Ch  
Initial Value: 0000\_FFFFh

Table 40.4-43 PFC\_P01\_SR Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 16     | SR_WE[15:00] | Enables write to SR[15:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 0      | SR[15:00]    | Set the PORT01 pin bit[15:00] SR value.<br>0b: Fast slew<br>1b: Slow slew                       |

40.4.2.25 PORT01 Input Data Mask Register (PFC\_P01\_DI\_MSK)

This register controls masking of input data of the PORT01 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0070h  
Initial Value: 0000\_FFFFh

Table 40.4-44 PFC\_P01\_DI\_MSK Register Contents

| Bit Position | Bit Name         | Description                                                                                                      |
|--------------|------------------|------------------------------------------------------------------------------------------------------------------|
| 31 to 16     | DI_MSK_WE[15:00] | Enables write to DI_MSK[15:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable              |
| 15 to 0      | DI_MSK[15:00]    | Set the PORT01 DI_MSK pin value bit[15:00].<br>0b: Remove masking of the input data.<br>1b: Mask the input data. |

40.4.2.26 PORT01 Input/Output Enable Mask Register (PFC\_P01\_EN\_MSK)

This register controls masking of input/output enable for the PORT01 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0074h  
Initial Value: 0000\_FFFFh

Table 40.4-45 PFC\_P01\_EN\_MSK Register Contents

| Bit Position | Bit Name          | Description                                                                                                                        |
|--------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 16     | EN_MSK_WE [15:00] | Enables write to EN_MSK[15:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable                                |
| 15 to 0      | EN_MSK[15:00]     | Set the PORT01 EN_MSK pin bit[15:00] value.<br>0b: Remove masking of the input/output enable.<br>1b: Mask the input/output enable. |

40.4.2.27 PORT02 GPIO Output Value Control Register (PFC\_P02\_GPIO\_DO)

This register controls the output value of GPIO PORT02.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0080h  
Initial Value: 0000\_0000h

|               |    |    |    |    |    |    |    |    |              |      |      |      |      |      |      |      |

Table 40.4-48 PFC\_P02\_GPIO\_IE Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 24     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 23 to 16     | IE_WE[07:00] | Enables write to IE[07:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 8      | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 7 to 0       | IE[07:00]    | Control the input of GPIO PORT02 pin bit[07:00].<br>0b: Disable input.<br>1b: Enable input.     |

#### 40.4.2.30 PORT02 Function Select Register 0 (PFC\_P02\_PFSEL0)

This register controls function selection of the multi-purpose pin in PORT02.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 0090h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30      | 29   | 28   | 27 | 26      | 25   | 24   | 23 | 22      | 21   | 20   | 19 | 18      | 17   | 16   |

**Remarks:** —: Setting prohibited

#### 40.4.2.31 PORT02 Function Select Register 1 (PFC\_P02\_PFSEL1)

This register controls function selection of the multi-purpose pin in PORT02.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 0094h

**Initial Value:** 0000\_0000h

**Remarks:** —: Setting prohibited

40.4.2.32 PORT02 Input Value Monitor Register (PFC\_P02\_DI\_MON)

This register is a read-only register that monitors the input value of the PORT02 input pin (P02\_DI).

Writing is ignored.

Immediately after reset, this register becomes 0000\_0000h.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 00A0h  
Initial Value: 0000\_00xxh

|               |    |    |    |    |    |    |    |    |           |    |    |    |    |    |    |    |

| Bit Position | Bit Name  | Description                                     |
|--------------|-----------|-------------------------------------------------|
| 31 to 8      | —         | Reserved. These bits are read as 0b.            |
| 7 to 0       | DI[07:00] | The input value of PORT02 input pin bit[07:00]. |

### 40.4.2.33 PORT02 Pull-Up/Down Control Register (PFC\_P02\_PUPD)

This register controls pulling up and down of the PORT02 pin.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 00A4h

**Initial Value:** 0000\_5555h

40.4.2.36 PORT02 Input Data Mask Register (PFC\_P02\_DI\_MSK)

This register controls masking of input data of the PORT02 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 00B0h  
Initial Value: 0000\_00FFh

Table 40.4-57 PFC\_P02\_DI\_MSK Register Contents

| Bit Position | Bit Name         | Description                                                                                                      |
|--------------|------------------|------------------------------------------------------------------------------------------------------------------|
| 31 to 24     | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 23 to 16     | DI_MSK_WE[07:00] | Enables write to DI_MSK[07:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable              |
| 15 to 8      | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 7 to 0       | DI_MSK[07:00]    | Set the PORT02 DI_MSK pin value bit[07:00].<br>0b: Remove masking of the input data.<br>1b: Mask the input data. |

40.4.2.37 PORT02 Input/Output Enable Mask Register (PFC\_P02\_EN\_MSK)

This register controls masking of input/output enable for the PORT02 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 00B4h  
Initial Value: 0000\_00FFh

| Bit Position | Bit Name          | Description                                                                                                                        |
|--------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 24     | —                 | Reserved. These bits are read as 0b. The write value should always be 0b.                                                          |
| 23 to 16     | EN_MSK_WE [07:00] | Enables write to EN_MSK[07:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable                                |
| 15 to 8      | —                 | Reserved. These bits are read as 0b. The write value should always be 0b.                                                          |
| 7 to 0       | EN_MSK[07:00]     | Set the PORT02 EN_MSK pin bit[07:00] value.<br>0b: Remove masking of the input/output enable.<br>1b: Mask the input/output enable. |

40.4.2.38 PORT03 GPIO Output Value Control Register (PFC\_P03\_GPIO\_DO)

This register controls the output value of PORT03 GPIO.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 00C0h  
Initial Value: 0000\_0000h

Table 40.4-59 PFC\_P03\_GPIO\_DO Register Contents

| Bit Position | Bit Name     | Description                                                                                      |
|--------------|--------------|--------------------------------------------------------------------------------------------------|
| 31 to 16     | DO_WE[15:00] | Enables write to DO[15:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable  |
| 15 to 0      | DO[15:00]    | Set the GPIO PORT03 bit[15:00] value.<br>0b: Output the low level.<br>1b: Output the high level. |

40.4.2.39 PORT03 GPIO Output Control Register (PFC\_P03\_GPIO\_OE)

This register controls whether GPIO PORT03 output is enabled or disabled.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 00C4h  
Initial Value: 0000\_0000h

Table 40.4-60 PFC\_P03\_GPIO\_OE Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 16     | OE_WE[15:00] | Enables write to OE[15:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 0      | OE[15:00]    | Control the output of GPIO PORT03 bit[15:00].<br>0b: Disable output.<br>1b: Enable output.      |

40.4.2.40 PORT03 GPIO Input Control Register (PFC\_P03\_GPIO\_IE)

This register controls whether GPIO PORT03 input is enabled or disabled.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 00C8h  
Initial Value: 0000\_0000h

Table 40.4-61 PFC\_P03\_GPIO\_IE Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 16     | IE_WE[15:00] | Enables write to IE[15:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 0      | IE[15:00]    | Control the input of GPIO PORT03 pin bit[15:00].<br>0b: Disable input.<br>1b: Enable input.     |

#### 40.4.2.41 PORT03 Function Select Register 0 (PFC\_P03\_PFSEL0)

This register controls function selection of the multi-purpose pin in PORT03.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 00D0h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30      | 29   | 28   | 27 | 26      | 25   | 24   | 23 | 22      | 21   | 20   | 19 | 18      | 17   | 16   |

**Remarks:** —: Setting prohibited

#### 40.4.2.43 PORT03 Function Select Register 2 (PFC\_P03\_PFSEL2)

This register controls function selection of the multi-purpose pin in PORT03.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 00D8h

**Initial Value:** 0000\_0000h

40.4.2.45 PORT03 Input Value Monitor Register (PFC\_P03\_DI\_MON)

This register is a read-only register that monitors the input value of the PORT03 input pin (P03\_DI).

Writing is ignored.

Immediately after reset, this register becomes 0000\_0000h.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 00E0h  
Initial Value: 0000\_xxxxh

Table 40.4-70 PFC\_P03\_DI\_MON Register Contents

| Bit Position | Bit Name  | Description                                     |
|--------------|-----------|-------------------------------------------------|
| 31 to 16     | —         | Reserved. These bits are read as 0b.            |
| 15 to 0      | DI[15:00] | The input value of PORT03 input pin bit[15:00]. |

40.4.2.46 PORT03 Pull-Up/Down Control Register (PFC\_P03\_PUPD)

This register controls pulling up and down of the PORT03 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 00E4h  
Initial Value: 0055\_5555h

|               |        |    |        |    |        |    |        |    |        |    |        |    |        |    |        |    |
|---------------|--------|----|--------|----|--------|----|--------|----|--------|----|--------|----|--------|----|--------|----|

| Bit Position | Bit Name    | Description                                                                                                                         |
|--------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | PUPD[15:00] | Control PORT03 pin bit[15:00] I/O buffer pull-up/down.<br>x1b: No pull-up/down<br>00b: Pull-down<br>10b: Pull-up<br>(x: Don't care) |

40.4.2.47 PORT03 Drive Strength Control Register (PFC\_P03\_DRV)

This register controls the drive strength of the PORT03 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 00E8h  
Initial Value: 5555\_5555h

|               |       |    |       |    |       |    |       |    |       |    |       |    |       |    |       |    |

|--------------|------------|----------------------------------------------------------------------------------------------------------|
| 31 to 0      | DRV[15:00] | Control the PORT03 pin bit[15:00] I/O buffer drive strength.<br>00b: X1<br>01b: X2<br>10b: X4<br>11b: X6 |

40.4.2.48 PORT03 Slew-rate Control Register (PFC\_P03\_SR)

This register controls the slew-rate of the PORT03 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 00ECh  
Initial Value: 0000\_FFFFh

Table 40.4-73 PFC\_P03\_SR Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 16     | SR_WE[15:00] | Enables write to SR[15:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 0      | SR[15:00]    | Set the PORT03 pin bit[15:00] SR value.<br>0b: Fast slew<br>1b: Slow slew                       |

40.4.2.49 PORT03 Input Data Mask Register (PFC\_P03\_DI\_MSK)

This register controls masking of input data of the PORT03 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 00F0h  
Initial Value: 0000\_FFFFh

Table 40.4-74 PFC\_P03\_DI\_MSK Register Contents

| Bit Position | Bit Name         | Description                                                                                                      |
|--------------|------------------|------------------------------------------------------------------------------------------------------------------|
| 31 to 16     | DI_MSK_WE[15:00] | Enables write to DI_MSK[15:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable              |
| 15 to 0      | DI_MSK[15:00]    | Set the PORT03 DI_MSK pin value bit[15:00].<br>0b: Remove masking of the input data.<br>1b: Mask the input data. |

40.4.2.50 PORT03 Input/Output Enable Mask Register (PFC\_P03\_EN\_MSK)

This register controls masking of input/output enable for the PORT03 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 00F4h  
Initial Value: 0000\_FFFFh

Table 40.4-75 PFC\_P03\_EN\_MSK Register Contents

| Bit Position | Bit Name          | Description                                                                                                                        |
|--------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 16     | EN_MSK_WE [15:00] | Enables write to EN_MSK[15:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable                                |
| 15 to 0      | EN_MSK[15:00]     | Set the PORT03 EN_MSK pin bit[15:00] value.<br>0b: Remove masking of the input/output enable.<br>1b: Mask the input/output enable. |

40.4.2.51 PORT04 GPIO Output Value Control Register (PFC\_P04\_GPIO\_DO)

This register controls the output value of GPIO PORT04.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0100h  
Initial Value: 0000\_0000h

Table 40.4-76 PFC\_P04\_GPIO\_DO Register Contents

| Bit Position | Bit Name     | Description                                                                                      |
|--------------|--------------|--------------------------------------------------------------------------------------------------|
| 31 to 24     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                        |
| 23 to 16     | DO_WE[07:00] | Enables write to DO[07:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable  |
| 15 to 8      | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                        |
| 7 to 0       | DO[07:00]    | Set the GPIO PORT04 bit[07:00] value.<br>0b: Output the low level.<br>1b: Output the high level. |

40.4.2.52 PORT04 GPIO Output Control Register (PFC\_P04\_GPIO\_OE)

This register controls whether GPIO PORT04 output is enabled or disabled.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0104h  
Initial Value: 0000\_0000h

|               |    |    |    |    |    |    |    |    |              |      |      |      |      |      |      |      |

| 15 to 8      | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 7 to 0       | OE[07:00]    | Control the output of GPIO PORT04 bit[07:00].<br>0b: Disable output.<br>1b: Enable output.      |

40.4.2.53 PORT04 GPIO Input Control Register (PFC\_P04\_GPIO\_IE)

This register controls whether GPIO PORT04 input is enabled or disabled.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0108h  
Initial Value: 0000\_0000h

|               |    |    |    |    |    |    |    |    |              |      |      |      |      |      |      |      |

Table 40.4-78 PFC\_P04\_GPIO\_IE Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 24     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 23 to 16     | IE_WE[07:00] | Enables write to IE[07:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 8      | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 7 to 0       | IE[07:00]    | Control the input of GPIO PORT04 pin bit[07:00].<br>0b: Disable input.<br>1b: Enable input.     |

#### 40.4.2.54 PORT04 Function Select Register 0 (PFC\_P04\_PFSEL0)

This register controls function selection of the multi-purpose pin in PORT04.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 0110h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30      | 29   | 28   | 27 | 26      | 25   | 24   | 23 | 22      | 21   | 20   | 19 | 18      | 17   | 16   |

**Remarks:** —: Setting prohibited

#### 40.4.2.55 PORT04 Function Select Register 1 (PFC\_P04\_PFSEL1)

This register controls function selection of the multi-purpose pin in PORT04.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 0114h

**Initial Value:** 0000\_0000h

40.4.2.56 PORT04 Input Value Monitor Register (PFC\_P04\_DI\_MON)

This register is a read-only register that monitors the input value of the PORT04 input pin (P04\_DI).

Writing is ignored.

Immediately after reset, this register becomes 0000\_0000h.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 00120h  
Initial Value: 0000\_00xxh

40.4.2.57 PORT04 Pull-Up/Down Control Register (PFC\_P04\_PUPD)

This register controls pulling up and down of the PORT04 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0124h  
Initial Value: 0000\_0000h

|               |        |        |        |        |        |        |        |        |    |    |    |    |    |    |    |    |

| 15 to 8      | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 7 to 0       | SR[07:00]    | Set the PORT04 pin bit[07:00] SR value.<br>0b: Fast slew<br>1b: Slow slew                       |

40.4.2.60 PORT04 Input Data Mask Register (PFC\_P04\_DI\_MSK)

This register controls masking of input data of the PORT04 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0130h  
Initial Value: 0000\_00FFh

Table 40.4-87 PFC\_P04\_DI\_MSK Register Contents

| Bit Position | Bit Name         | Description                                                                                                      |
|--------------|------------------|------------------------------------------------------------------------------------------------------------------|
| 31 to 24     | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 23 to 16     | DI_MSK_WE[07:00] | Enables write to DI_MSK[07:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable              |
| 15 to 8      | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 7 to 0       | DI_MSK[07:00]    | Set the PORT04 DI_MSK pin value bit[07:00].<br>0b: Remove masking of the input data.<br>1b: Mask the input data. |

40.4.2.61 PORT04 Input/Output Enable Mask Register (PFC\_P04\_EN\_MSK)

This register controls masking of input/output enable for the PORT04 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0134h  
Initial Value: 0000\_00FFh

Table 40.4-88 PFC\_P04\_EN\_MSK Register Contents

| Bit Position | Bit Name          | Description                                                                                                                        |
|--------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 24     | —                 | Reserved. These bits are read as 0b. The write value should always be 0b.                                                          |
| 23 to 16     | EN_MSK_WE [07:00] | Enables write to EN_MSK[07:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable                                |
| 15 to 8      | —                 | Reserved. These bits are read as 0b. The write value should always be 0b.                                                          |
| 7 to 0       | EN_MSK[07:00]     | Set the PORT04 EN_MSK pin bit[07:00] value.<br>0b: Remove masking of the input/output enable.<br>1b: Mask the input/output enable. |

40.4.2.62 PORT05 GPIO Output Value Control Register (PFC\_P05\_GPIO\_DO)

This register controls the output value of GPIO PORT05.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0140h  
Initial Value: 0000\_0000h

|               |    |    |    |    |    |    |    |    |    |    |    |    |              |      |      |      |

**Remarks:** —: Setting prohibited

40.4.2.66 PORT05 Input Value Monitor Register (PFC\_P05\_DI\_MON)

This register is a read-only register that monitors the input value of the PORT05 input pin (P02\_DI).

Writing is ignored.

Immediately after reset, this register becomes 0000\_0000h.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0160h  
Initial Value: 0000\_000xh

|--------------|-----------|-------------------------------------------------|
| 31 to 4      | —         | Reserved. These bits are read as 0b.            |
| 3 to 0       | DI[03:00] | The input value of PORT05 input pin bit[03:00]. |

40.4.2.67 PORT05 Pull-Up/Down Control Register (PFC\_P05\_PUPD)

This register controls pulling up and down of the PORT05 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0164h  
Initial Value: 0000\_0055h

|               |    |    |    |    |    |    |    |    |        |    |        |    |        |    |        |    |

|--------------|------------------|------------------------------------------------------------------------------------------------------------------|
| 31 to 20     | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 19 to 16     | DI_MSK_WE[03:00] | Enables write to DI_MSK[03:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable              |
| 15 to 4      | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 3 to 0       | DI_MSK[03:00]    | Set the PORT05 DI_MSK pin value bit[03:00].<br>0b: Remove masking of the input data.<br>1b: Mask the input data. |

40.4.2.71 PORT05 Input/Output Enable Mask Register (PFC\_P05\_EN\_MSK)

This register controls masking of input/output enable for the PORT05 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0174h  
Initial Value: 0000\_000Fh

|--------------|----------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 20     | —                    | Reserved. These bits are read as 0b. The write value should always be 0b.                                                          |
| 19 to 16     | EN_MSK_WE<br>[03:00] | Enables write to EN_MSK[03:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable                                |
| 15 to 4      | —                    | Reserved. These bits are read as 0b. The write value should always be 0b.                                                          |
| 3 to 0       | EN_MSK[03:00]        | Set the PORT05 EN_MSK pin bit[03:00] value.<br>0b: Remove masking of the input/output enable.<br>1b: Mask the input/output enable. |

40.4.2.72 PORT06 GPIO Output Value Control Register (PFC\_P06\_GPIO\_DO)

This register controls the output value of PORT06 GPIO.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0180h  
Initial Value: 0000\_0000h

Table 40.4-100 PFC\_P06\_GPIO\_DO Register Contents

| Bit Position | Bit Name     | Description                                                                                      |
|--------------|--------------|--------------------------------------------------------------------------------------------------|
| 31 to 28     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                        |
| 27 to 16     | DO_WE[11:00] | Enables write to DO[11:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable  |
| 15 to 12     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                        |
| 11 to 0      | DO[11:00]    | Set the GPIO PORT06 bit[11:00] value.<br>0b: Output the low level.<br>1b: Output the high level. |

40.4.2.73 PORT06 GPIO Output Control Register (PFC\_P06\_GPIO\_OE)

This register controls whether GPIO PORT06 output is enabled or disabled.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0184h  
Initial Value: 0000\_0000h

Table 40.4-101 PFC\_P06\_GPIO\_OE Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 28     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 27 to 16     | OE_WE[11:00] | Enables write to OE[11:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 12     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 11 to 0      | OE[11:00]    | Control the output of GPIO PORT06 bit[11:00].<br>0b: Disable output.<br>1b: Enable output.      |

40.4.2.74 PORT06 GPIO Input Control Register (PFC\_P06\_GPIO\_IE)

This register controls whether GPIO PORT06 input is enabled or disabled.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0188h  
Initial Value: 0000\_0000h

Table 40.4-102 PFC\_P06\_GPIO\_IE Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 28     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 27 to 16     | IE_WE[11:00] | Enables write to IE[11:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 12     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 11 to 0      | IE[11:00]    | Control the input of GPIO PORT06 pin bit[11:00].<br>0b: Disable input.<br>1b: Enable input.     |

#### 40.4.2.75 PORT06 Function Select Register 0 (PFC\_P06\_PFSEL0)

This register controls function selection of the multi-purpose pin in PORT06.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 0190h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30      | 29   | 28   | 27 | 26      | 25   | 24   | 23 | 22      | 21   | 20   | 19 | 18      | 17   | 16   |

**Remarks:** —: Setting prohibited

40.4.2.78 PORT06 Input Value Monitor Register (PFC\_P06\_DI\_MON)

This register is a read-only register that monitors the input value of the PORT06 input pin (P06\_DI).

Writing is ignored.

Immediately after reset, this register becomes 0000\_0000h.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 01A0h  
Initial Value: 0000\_0xxxh

| Bit Position | Bit Name  | Description                                     |
|--------------|-----------|-------------------------------------------------|
| 31 to 12     | —         | Reserved. These bits are read as 0b.            |
| 11 to 0      | DI[11:00] | The input value of PORT06 input pin bit[11:00]. |

### 40.4.2.79 PORT06 Pull-Up/Down Control Register (PFC\_P06\_PUPD)

This register controls pulling up and down of the PORT06 pin.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 01A4h

**Initial Value:** 0055\_5555h

Table 40.4-112 PFC\_P06\_SR Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 28     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 27 to 16     | SR_WE[11:00] | Enables write to SR[11:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 12     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 11 to 0      | SR[11:00]    | Set the PORT06 pin bit[11:00] SR value.<br>0b: Fast slew<br>1b: Slow slew                       |

40.4.2.82 PORT06 Input Data Mask Register (PFC\_P06\_DI\_MSK)

This register controls masking of input data of the PORT06 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 01B0h  
Initial Value: 0000\_0FFFh

Table 40.4-113 PFC\_P06\_DI\_MSK Register Contents

| Bit Position | Bit Name         | Description                                                                                                      |
|--------------|------------------|------------------------------------------------------------------------------------------------------------------|
| 31 to 28     | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 27 to 16     | DI_MSK_WE[11:00] | Enables write to DI_MSK[11:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable              |
| 15 to 12     | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 11 to 0      | DI_MSK[11:00]    | Set the PORT06 DI_MSK pin value bit[11:00].<br>0b: Remove masking of the input data.<br>1b: Mask the input data. |

40.4.2.83 PORT06 Input/Output Enable Mask Register (PFC\_P06\_EN\_MSK)

This register controls masking of input/output enable for the PORT06 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 01B4h  
Initial Value: 0000\_0FFFh

|               |    |    |    |    |                  |      |      |      |      |      |      |      |      |      |      |      |

**Remarks:** —: Setting prohibited

40.4.2.89 PORT07 Input Value Monitor Register (PFC\_P07\_DI\_MON)

This register is a read-only register that monitors the input value of the PORT07 input pin (P07\_DI).

Writing is ignored.

Immediately after reset, this register becomes 0000\_0000h.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 01E0h  
Initial Value: 0000\_00xxh

|               |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |    |

Table 40.4-122 PFC\_P07\_DI\_MON Register Contents

| Bit Position | Bit Name  | Description                                     |
|--------------|-----------|-------------------------------------------------|
| 31 to 6      | —         | Reserved. These bits are read as 0b.            |
| 5 to 0       | DI[05:00] | The input value of PORT07 input pin bit[05:00]. |

40.4.2.90 PORT07 Pull-Up/Down Control Register (PFC\_P07\_PUPD)

This register controls pulling up and down of the PORT07 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 01E4h  
Initial Value: 0000\_0005h

|               |    |    |    |    |        |        |        |        |        |        |    |    |    |    |    |    |

### 40.4.2.92 PORT07 Slew-rate Control Register (PFC\_P07\_SR)

This register controls the slew-rate of the PORT07 pin.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 01ECh

**Initial Value:** 0000\_03Fh

| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21           | 20   | 19   | 18   | 17   | 16   |
|---------------|----|----|----|----|----|----|----|----|----|----|--------------|------|------|------|------|------|

Table 40.4-125 PFC\_P07\_SR Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 22     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 21 to 16     | SR_WE[05:00] | Enables write to SR[05:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 6      | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 5 to 0       | SR[05:00]    | Set the PORT07 pin bit[05:00] SR value.<br>0b: Fast slew<br>1b: Slow slew                       |

40.4.2.93 PORT07 Input Data Mask Register (PFC\_P07\_DI\_MSK)

This register controls masking of input data of the PORT07 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 01F0h  
Initial Value: 0000\_003Fh

|               |    |    |    |    |    |    |    |    |    |    |                  |      |      |      |      |      |

Table 40.4-126 PFC\_P07\_DI\_MSK Register Contents

| Bit Position | Bit Name         | Description                                                                                                      |
|--------------|------------------|------------------------------------------------------------------------------------------------------------------|
| 31 to 22     | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 21 to 16     | DI_MSK_WE[05:00] | Enables write to DI_MSK[05:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable              |
| 15 to 6      | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 5 to 0       | DI_MSK[05:00]    | Set the PORT07 DI_MSK pin value bit[05:00].<br>0b: Remove masking of the input data.<br>1b: Mask the input data. |

#### 40.4.2.94 PORT07 Input/Output Enable Mask Register (PFC\_P07\_EN\_MSK)

This register controls masking of input/output enable for the PORT07 pin.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 01F4h

**Initial Value:** 0000\_003Fh

|               |    |    |    |    |    |    |    |    |    |    |                  |      |      |      |      |      |

40.4.2.95 PORT08 GPIO Output Value Control Register (PFC\_P08\_GPIO\_DO)

This register controls the output value of GPIO PORT08.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0200h  
Initial Value: 0000\_0000h

|               |    |    |    |    |    |    |    |    |              |      |      |      |      |      |      |      |

#### 40.4.2.99 PORT08 Function Select Register 1 (PFC\_P08\_PFSEL1)

This register controls function selection of the multi-purpose pin in PORT08.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 0214h

**Initial Value:** 0000\_0000h

40.4.2.100 PORT08 Input Value Monitor Register (PFC\_P08\_DI\_MON)

This register is a read-only register that monitors the input value of the PORT08 input pin (P08\_DI).

Writing is ignored.

Immediately after reset, this register becomes 0000\_0000h.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0220h  
Initial Value: 0000\_00xxh

#### 40.4.2.102 PORT08 Drive Strength Control Register (PFC\_P08\_DRV)

This register controls the drive strength of the PORT08 pin.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 0228h

**Initial Value:** 0000\_5000h

|               |       |    |       |    |       |    |       |    |       |    |       |    |       |    |       |    |

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 24     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 23 to 16     | SR_WE[07:00] | Enables write to SR[07:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 8      | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 7 to 0       | SR[07:00]    | Set the PORT08 pin bit[07:00] SR value.<br>0b: Fast slew<br>1b: Slow slew                       |

40.4.2.104 PORT08 Input Data Mask Register (PFC\_P08\_DI\_MSK)

This register controls masking of input data of the PORT08 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0230h  
Initial Value: 0000\_00FFh

Table 40.4-139 PFC\_P08\_DI\_MSK Register Contents

| Bit Position | Bit Name         | Description                                                                                                      |
|--------------|------------------|------------------------------------------------------------------------------------------------------------------|
| 31 to 24     | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 23 to 16     | DI_MSK_WE[07:00] | Enables write to DI_MSK[07:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable              |
| 15 to 8      | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 7 to 0       | DI_MSK[07:00]    | Set the PORT08 DI_MSK pin value bit[07:00].<br>0b: Remove masking of the input data.<br>1b: Mask the input data. |

40.4.2.105 PORT08 Input/Output Enable Mask Register (PFC\_P08\_EN\_MSK)

This register controls masking of input/output enable for the PORT08 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0234h  
Initial Value: 0000\_00FFh

|               |    |    |    |    |    |    |    |    |                  |      |      |      |      |      |      |      |

| 15 to 8      | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 7 to 0       | OE[07:00]    | Control the output of GPIO PORT09 bit[07:00].<br>0b: Disable output.<br>1b: Enable output.      |

40.4.2.108 PORT09 GPIO Input Control Register (PFC\_P09\_GPIO\_IE)

This register controls whether GPIO PORT09 input is enabled or disabled.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0248h  
Initial Value: 0000\_0000h

|               |    |    |    |    |    |    |    |    |              |      |      |      |      |      |      |      |

**Remarks:** —: Setting prohibited

40.4.2.111 PORT09 Input Value Monitor Register (PFC\_P09\_DI\_MON)

This register is a read-only register that monitors the input value of the PORT09 input pin (P09\_DI).

Writing is ignored.

Immediately after reset, this register becomes 0000\_0000h.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0260h  
Initial Value: 0000\_00xxh

|               |    |    |    |    |    |    |    |    |           |    |    |    |    |    |    |    |

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 24     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 23 to 16     | SR_WE[07:00] | Enables write to SR[07:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 8      | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 7 to 0       | SR[07:00]    | Set the PORT09 pin bit[07:00] SR value.<br>0b: Fast slew<br>1b: Slow slew                       |

40.4.2.115 PORT09 Input Data Mask Register (PFC\_P09\_DI\_MSK)

This register controls masking of input data of the PORT09 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0270h  
Initial Value: 0000\_00FFh

Table 40.4-152 PFC\_P09\_DI\_MSK Register Contents

| Bit Position | Bit Name         | Description                                                                                                      |
|--------------|------------------|------------------------------------------------------------------------------------------------------------------|
| 31 to 24     | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 23 to 16     | DI_MSK_WE[07:00] | Enables write to DI_MSK[07:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable              |
| 15 to 8      | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 7 to 0       | DI_MSK[07:00]    | Set the PORT09 DI_MSK pin value bit[07:00].<br>0b: Remove masking of the input data.<br>1b: Mask the input data. |

40.4.2.116 PORT09 Input/Output Enable Mask Register (PFC\_P09\_EN\_MSK)

This register controls masking of input/output enable for the PORT09 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0274h  
Initial Value: 0000\_00FFh

|--------------|----------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 24     | —                    | Reserved. These bits are read as 0b. The write value should always be 0b.                                                          |
| 23 to 16     | EN_MSK_WE<br>[07:00] | Enables write to EN_MSK[07:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable                                |
| 15 to 8      | —                    | Reserved. These bits are read as 0b. The write value should always be 0b.                                                          |
| 7 to 0       | EN_MSK[07:00]        | Set the PORT09 EN_MSK pin bit[07:00] value.<br>0b: Remove masking of the input/output enable.<br>1b: Mask the input/output enable. |

40.4.2.117 PORT10 GPIO Output Value Control Register (PFC\_P10\_GPIO\_DO)

This register controls the output value of PORT10 GPIO.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0280h  
Initial Value: 0000\_0000h

Table 40.4-154 PFC\_P10\_GPIO\_DO Register Contents

| Bit Position | Bit Name     | Description                                                                                      |
|--------------|--------------|--------------------------------------------------------------------------------------------------|
| 31 to 25     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                        |
| 24 to 16     | DO_WE[08:00] | Enables write to DO[08:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable  |
| 15 to 9      | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                        |
| 8 to 0       | DO[08:00]    | Set the GPIO PORT10 bit[08:00] value.<br>0b: Output the low level.<br>1b: Output the high level. |

40.4.2.118 PORT10 GPIO Output Control Register (PFC\_P10\_GPIO\_OE)

This register controls whether GPIO PORT10 output is enabled or disabled.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0284h  
Initial Value: 0000\_0000h

Table 40.4-155 PFC\_P10\_GPIO\_OE Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 25     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 24 to 16     | OE_WE[08:00] | Enables write to OE[08:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 9      | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 8 to 0       | OE[08:00]    | Control the output of GPIO PORT10 bit[08:00].<br>0b: Disable output.<br>1b: Enable output.      |

40.4.2.119 PORT10 GPIO Input Control Register (PFC\_P10\_GPIO\_IE)

This register controls whether GPIO PORT10 input is enabled or disabled.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0288h  
Initial Value: 0000\_0000h

|               |    |    |    |    |    |    |    |              |      |      |      |      |      |      |      |      |

**Remarks:** —: Setting prohibited

#### 40.4.2.121 PORT10 Function Select Register 1 (PFC\_P10\_PFSEL1)

This register controls function selection of the multi-purpose pin in PORT10.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 0294h

**Initial Value:** 0000\_0000h

#### 40.4.2.122 PORT10 Function Select Register 2 (PFC\_P10\_PFSEL2)

This register controls function selection of the multi-purpose pin in PORT10.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 0298h

**Initial Value:** 0000\_0000h

40.4.2.123 PORT10 Input Value Monitor Register (PFC\_P10\_DI\_MON)

This register is a read-only register that monitors the input value of the PORT10 input pin (P10\_DI).

Writing is ignored.

Immediately after reset, this register becomes 0000\_0000h.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 02A0h  
Initial Value: 0000\_0xxxh

|               |    |    |    |    |    |    |    |           |    |    |    |    |    |    |    |    |

| 24 to 16     | SR_WE[08:00] | Enables write to SR[08:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 9      | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 8 to 0       | SR[08:00]    | Set the PORT10 pin bit[08:00] SR value.<br>0b: Fast slew<br>1b: Slow slew                       |

40.4.2.127 PORT10 Input Data Mask Register (PFC\_P10\_DI\_MSK)

This register controls masking of input data of the PORT10 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 02B0h  
Initial Value: 0000\_01FFh

|               |    |    |    |    |    |    |    |                  |      |      |      |      |      |      |      |      |

|--------------|------------------|------------------------------------------------------------------------------------------------------------------|
| 31 to 25     | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 24 to 16     | DI_MSK_WE[08:00] | Enables write to DI_MSK[08:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable              |
| 15 to 9      | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 8 to 0       | DI_MSK[08:00]    | Set the PORT10 DI_MSK pin value bit[08:00].<br>0b: Remove masking of the input data.<br>1b: Mask the input data. |

#### 40.4.2.128 PORT10 Input/Output Enable Mask Register (PFC\_P10\_EN\_MSK)

This register controls masking of input/output enable for the PORT10 pin.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 02B4h

**Initial Value:** 0000\_01FFh

| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24                | 23                | 22                | 21                | 20                | 19                | 18                | 17                | 16                |

Table 40.4-168 PFC\_P10\_EN\_MSK Register Contents

| Bit Position | Bit Name         | Description                                                                                                                        |
|--------------|------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 25     | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                                          |
| 24 to 16     | EN_MSK_WE[08:00] | Enables write to EN_MSK[08:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable                                |
| 15 to 9      | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                                          |
| 8 to 0       | EN_MSK[08:00]    | Set the PORT10 EN_MSK pin bit[08:00] value.<br>0b: Remove masking of the input/output enable.<br>1b: Mask the input/output enable. |

40.4.2.129 PORT11 GPIO Output Value Control Register (PFC\_P11\_GPIO\_DO)

This register controls the output value of PORT11 GPIO.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 02C0h  
Initial Value: 0000\_0000h

Table 40.4-169 PFC\_P11\_GPIO\_DO Register Contents

| Bit Position | Bit Name     | Description                                                                                      |
|--------------|--------------|--------------------------------------------------------------------------------------------------|
| 31 to 25     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                        |
| 24 to 16     | DO_WE[08:00] | Enables write to DO[08:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable  |
| 15 to 9      | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                        |
| 8 to 0       | DO[08:00]    | Set the GPIO PORT11 bit[08:00] value.<br>0b: Output the low level.<br>1b: Output the high level. |

40.4.2.130 PORT11 GPIO Output Control Register (PFC\_P11\_GPIO\_OE)

This register controls whether GPIO PORT11 output is enabled or disabled.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 02C4h  
Initial Value: 0000\_0000h

|               |    |    |    |    |    |    |    |              |      |      |      |      |      |      |      |      |

**Remarks:** —: Setting prohibited

#### 40.4.2.133 PORT11 Function Select Register 1 (PFC\_P11\_PFSEL1)

This register controls function selection of the multi-purpose pin in PORT11.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 02D4h

**Initial Value:** 0000\_0000h

**Remarks:** —: Setting prohibited

40.4.2.135 PORT11 Input Value Monitor Register (PFC\_P11\_DI\_MON)

This register is a read-only register that monitors the input value of the PORT11 input pin (P11\_DI).

Writing is ignored.

Immediately after reset, this register becomes 0000\_0000h.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 02E0h  
Initial Value: 0000\_0xxxh

|               |    |    |    |    |    |    |    |           |    |    |    |    |    |    |    |    |

| Bit Position | Bit Name  | Description                                                               |
|--------------|-----------|---------------------------------------------------------------------------|
| 31 to 9      | —         | Reserved. These bits are read as 0b. The write value should always be 0b. |
| 8 to 0       | DI[08:00] | The input value of PORT11 input pin bit[08:00].                           |

#### 40.4.2.136 PORT11 Pull-Up/Down Control Register (PFC\_P11\_PUPD)

This register controls pulling up and down of the PORT11 pin.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 02E4h

**Initial Value:** 0001\_5110h

|               |        |    |        |    |        |    |        |    |        |    |        |    |        |    |        |    |

**Remarks:** —: Setting prohibited

40.4.2.145 PORT12 Input Value Monitor Register (PFC\_P12\_DI\_MON)

This register is a read-only register that monitors the input value of the PORT12 input pin (P02\_DI).

Writing is ignored.

Immediately after reset, this register becomes 0000\_0000h.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0320h  
Initial Value: 0000\_000xh

40.4.2.148 PORT12 Slew-rate Control Register (PFC\_P12\_SR)

This register controls the slew-rate of the PORT12 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 032Ch  
Initial Value: 0000\_000Fh

|               |    |    |    |    |    |    |    |    |    |    |    |    |              |      |      |      |

| Bit Position | Bit Name         | Description                                                                                                      |
|--------------|------------------|------------------------------------------------------------------------------------------------------------------|
| 31 to 20     | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 19 to 16     | DI_MSK_WE[03:00] | Enables write to DI_MSK[03:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable              |
| 15 to 4      | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 3 to 0       | DI_MSK[03:00]    | Set the PORT12 DI_MSK pin value bit[03:00].<br>0b: Remove masking of the input data.<br>1b: Mask the input data. |

#### 40.4.2.150 PORT12 Input/Output Enable Mask Register (PFC\_P12\_EN\_MSK)

This register controls masking of input/output enable for the PORT12 pin.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 0334h

**Initial Value:** 0000\_000Fh

|               |    |    |    |    |    |    |    |    |    |    |    |    |                  |      |      |      |

| Bit Position | Bit Name             | Description                                                                                                                        |
|--------------|----------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 20     | —                    | Reserved. These bits are read as 0b. The write value should always be 0b.                                                          |
| 19 to 16     | EN_MSK_WE<br>[03:00] | Enables write to EN_MSK[03:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable                                |
| 15 to 4      | —                    | Reserved. These bits are read as 0b. The write value should always be 0b.                                                          |
| 3 to 0       | EN_MSK[03:00]        | Set the PORT12 EN_MSK pin bit[03:00] value.<br>0b: Remove masking of the input/output enable.<br>1b: Mask the input/output enable. |

40.4.2.151 PORT13 GPIO Output Value Control Register (PFC\_P13\_GPIO\_DO)

This register controls the output value of PORT13 GPIO.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0340h  
Initial Value: 0000\_0000h

Table 40.4-195 PFC\_P13\_GPIO\_DO Register Contents

| Bit Position | Bit Name     | Description                                                                                      |
|--------------|--------------|--------------------------------------------------------------------------------------------------|
| 31 to 28     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                        |
| 27 to 16     | DO_WE[11:00] | Enables write to DO[11:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable  |
| 15 to 12     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                        |
| 11 to 0      | DO[11:00]    | Set the GPIO PORT13 bit[11:00] value.<br>0b: Output the low level.<br>1b: Output the high level. |

40.4.2.152 PORT13 GPIO Output Control Register (PFC\_P13\_GPIO\_OE)

This register controls whether GPIO PORT13 output is enabled or disabled.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0344h  
Initial Value: 0000\_0000h

Table 40.4-196 PFC\_P13\_GPIO\_OE Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 28     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 27 to 16     | OE_WE[11:00] | Enables write to OE[11:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 12     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 11 to 0      | OE[11:00]    | Control the output of GPIO PORT13 bit[11:00].<br>0b: Disable output.<br>1b: Enable output.      |

40.4.2.153 PORT13 GPIO Input Control Register (PFC\_P13\_GPIO\_IE)

This register controls whether GPIO PORT13 input is enabled or disabled.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0348h  
Initial Value: 0000\_0000h

|               |    |    |    |    |              |      |      |      |      |      |      |      |      |      |      |      |

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 28     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 27 to 16     | IE_WE[11:00] | Enables write to IE[11:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 12     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 11 to 0      | IE[11:00]    | Control the input of GPIO PORT13 pin bit[11:00].<br>0b: Disable input.<br>1b: Enable input.     |

#### 40.4.2.154 PORT13 Function Select Register 0 (PFC\_P13\_PFSEL0)

This register controls function selection of the multi-purpose pin in PORT13.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 0350h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30      | 29   | 28   | 27 | 26      | 25   | 24   | 23 | 22      | 21   | 20   | 19 | 18      | 17   | 16   |

**Remarks:** —: Setting prohibited

#### 40.4.2.155 PORT13 Function Select Register 1 (PFC\_P13\_PFSEL1)

This register controls function selection of the multi-purpose pin in PORT13.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 0354h

**Initial Value:** 0000\_0000h

40.4.2.157 PORT13 Input Value Monitor Register (PFC\_P13\_DI\_MON)

This register is a read-only register that monitors the input value of the PORT13 input pin (P13\_DI).

Writing is ignored.

Immediately after reset, this register becomes 0000\_0000h.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0360h  
Initial Value: 0000\_0xxxh

40.4.2.160 PORT13 Slew-rate Control Register (PFC\_P13\_SR)

This register controls the slew-rate of the PORT13 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 036Ch  
Initial Value: 0000\_0FFFh

Table 40.4-207 PFC\_P13\_SR Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 28     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 27 to 16     | SR_WE[11:00] | Enables write to SR[11:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 12     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 11 to 0      | SR[11:00]    | Set the PORT13 pin bit[11:00] SR value.<br>0b: Fast slew<br>1b: Slow slew                       |

40.4.2.161 PORT13 Input Data Mask Register (PFC\_P13\_DI\_MSK)

This register controls masking of input data of the PORT13 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0370h  
Initial Value: 0000\_0FFFh

Table 40.4-208 PFC\_P13\_DI\_MSK Register Contents

| Bit Position | Bit Name        | Description                                                                                                     |
|--------------|-----------------|-----------------------------------------------------------------------------------------------------------------|
| 31 to 28     | —               | Reserved. These bits are read as 0b. The write value should always be 0b.                                       |
| 27 to 16     | DI_MSK_WE[11:0] | Enables write to DI_MSK[11:0].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable              |
| 15 to 12     | —               | Reserved. These bits are read as 0b. The write value should always be 0b.                                       |
| 11 to 0      | DI_MSK[11:0]    | Set the PORT13 DI_MSK pin value bit[11:0].<br>0b: Remove masking of the input data.<br>1b: Mask the input data. |

40.4.2.162 PORT13 Input/Output Enable Mask Register (PFC\_P13\_EN\_MSK)

This register controls masking of input/output enable for the PORT13 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0374h  
Initial Value: 0000\_0FFFh

|               |    |    |    |    |                  |      |      |      |      |      |      |      |      |      |      |      |

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 24     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 23 to 16     | OE_WE[07:00] | Enables write to OE[07:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 8      | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 7 to 0       | OE[07:00]    | Control the output of GPIO PORT14 bit[07:00].<br>0b: Disable output.<br>1b: Enable output.      |

40.4.2.165 PORT14 GPIO Input Control Register (PFC\_P14\_GPIO\_IE)

This register controls whether GPIO PORT14 input is enabled or disabled.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0388h  
Initial Value: 0000\_0000h

Table 40.4-212 PFC\_P14\_GPIO\_IE Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 24     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 23 to 16     | IE_WE[07:00] | Enables write to IE[07:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 8      | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 7 to 0       | IE[07:00]    | Control the input of GPIO PORT14 pin bit[07:00].<br>0b: Disable input.<br>1b: Enable input.     |

#### 40.4.2.166 PORT14 Function Select Register 0 (PFC\_P14\_PFSEL0)

This register controls function selection of the multi-purpose pin in PORT14.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 0390h

**Initial Value:** 0000\_0000h

**Remarks:** —: Setting prohibited

40.4.2.168 PORT14 Input Value Monitor Register (PFC\_P14\_DI\_MON)

This register is a read-only register that monitors the input value of the PORT14 input pin (P14\_DI).

Writing is ignored.

Immediately after reset, this register becomes 0000\_0000h.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 03A0h  
Initial Value: 0000\_00xxh

|               |    |    |    |    |    |    |    |    |           |    |    |    |    |    |    |    |

| Bit Position | Bit Name  | Description                                     |
|--------------|-----------|-------------------------------------------------|
| 31 to 8      | —         | Reserved. These bits are read as 0b.            |
| 7 to 0       | DI[07:00] | The input value of PORT14 input pin bit[07:00]. |

40.4.2.169 PORT14 Pull-Up/Down Control Register (PFC\_P14\_PUPD)

This register controls pulling up and down of the PORT14 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 03A4h  
Initial Value: 0000\_1111h

|               |        |        |        |        |        |        |        |        |    |    |    |    |    |    |    |    |

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 24     | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 23 to 16     | SR_WE[07:00] | Enables write to SR[07:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 8      | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 7 to 0       | SR[07:00]    | Set the PORT14 pin bit[07:00] SR value.<br>0b: Fast slew<br>1b: Slow slew                       |

40.4.2.172 PORT14 Input Data Mask Register (PFC\_P14\_DI\_MSK)

This register controls masking of input data of the PORT14 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 03B0h  
Initial Value: 0000\_00FFh

|               |    |    |    |    |    |    |    |    |                  |      |      |      |      |      |      |      |

40.4.2.173 PORT14 Input/Output Enable Mask Register (PFC\_P14\_EN\_MSK)

This register controls masking of input/output enable for the PORT14 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 03B4h  
Initial Value: 0000\_00FFh

|               |    |    |    |    |    |    |    |    |                  |      |      |      |      |      |      |      |

| Bit Position | Bit Name          | Description                                                                                                                        |
|--------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 24     | —                 | Reserved. These bits are read as 0b. The write value should always be 0b.                                                          |
| 23 to 16     | EN_MSK_WE [07:00] | Enables write to EN_MSK[07:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable                                |
| 15 to 8      | —                 | Reserved. These bits are read as 0b. The write value should always be 0b.                                                          |
| 7 to 0       | EN_MSK[07:00]     | Set the PORT14 EN_MSK pin bit[07:00] value.<br>0b: Remove masking of the input/output enable.<br>1b: Mask the input/output enable. |

40.4.2.174 PORT15 GPIO Output Value Control Register (PFC\_P15\_GPIO\_DO)

This register controls the output value of PORT15 GPIO.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 03C0h  
Initial Value: 0000\_0000h

Table 40.4-223 PFC\_P15\_GPIO\_DO Register Contents

| Bit Position | Bit Name     | Description                                                                                      |
|--------------|--------------|--------------------------------------------------------------------------------------------------|
| 31 to 16     | DO_WE[15:00] | Enables write to DO[15:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable  |
| 15 to 0      | DO[15:00]    | Set the GPIO PORT15 bit[15:00] value.<br>0b: Output the low level.<br>1b: Output the high level. |

40.4.2.175 PORT15 GPIO Output Control Register (PFC\_P15\_GPIO\_OE)

This register controls whether GPIO PORT15 output is enabled or disabled.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 03C4h  
Initial Value: 0000\_0000h

Table 40.4-224 PFC\_P15\_GPIO\_OE Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 16     | OE_WE[15:00] | Enables write to OE[15:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 0      | OE[15:00]    | Control the output of GPIO PORT15 bit[15:00].<br>0b: Disable output.<br>1b: Enable output.      |

40.4.2.176 PORT15 GPIO Input Control Register (PFC\_P15\_GPIO\_IE)

This register controls whether GPIO PORT15 input is enabled or disabled.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 03C8h  
Initial Value: 0000\_0000h

Table 40.4-225 PFC\_P15\_GPIO\_IE Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 16     | IE_WE[15:00] | Enables write to IE[15:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 0      | IE[15:00]    | Control the input of GPIO PORT15 pin bit[15:00].<br>0b: Disable input.<br>1b: Enable input.     |

#### 40.4.2.177 PORT15 Function Select Register 0 (PFC\_P15\_PFSEL0)

This register controls function selection of the multi-purpose pin in PORT15.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 03D0h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30      | 29   | 28   | 27 | 26      | 25   | 24   | 23 | 22      | 21   | 20   | 19 | 18      | 17   | 16   |

**Remarks:** —: Setting prohibited

#### 40.4.2.180 PORT15 Function Select Register 3 (PFC\_P15\_PFSEL3)

This register controls function selection of the multi-purpose pin in PORT15.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 03DCh

**Initial Value:** 0000\_0000h

**Remarks:** —: Setting prohibited

40.4.2.181 PORT15 Input Value Monitor Register (PFC\_P15\_DI\_MON)

This register is a read-only register that monitors the input value of the PORT15 input pin (P15\_DI).

Writing is ignored.

Immediately after reset, this register becomes 0000\_0000h.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 03E0h  
Initial Value: 0000\_xxxxh

|               |           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| Bit Position | Bit Name  | Description                                     |
|--------------|-----------|-------------------------------------------------|
| 31 to 16     | —         | Reserved. These bits are read as 0b.            |
| 15 to 0      | DI[15:00] | The input value of PORT15 input pin bit[15:00]. |

40.4.2.182 PORT15 Pull-Up/Down Control Register (PFC\_P15\_PUPD)

This register controls pulling up and down of the PORT15 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 03E4h  
Initial Value: 5555\_5555h

|               |        |    |        |    |        |    |        |    |        |    |        |    |        |    |        |    |

40.4.2.184 PORT15 Slew-rate Control Register (PFC\_P15\_SR)

This register controls the slew-rate of the PORT15 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 03ECh  
Initial Value: 0000\_FFFFh

Table 40.4-237 PFC\_P15\_SR Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31 to 16     | SR_WE[15:00] | Enables write to SR[15:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15 to 0      | SR[15:00]    | Set the PORT15 pin bit[15:00] SR value.<br>0b: Fast slew<br>1b: Slow slew                       |

40.4.2.185 PORT15 Input Data Mask Register (PFC\_P15\_DI\_MSK)

This register controls masking of input data of the PORT15 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 03F0h  
Initial Value: 0000\_FFFFh

Table 40.4-238 PFC\_P15\_DI\_MSK Register Contents

| Bit Position | Bit Name        | Description                                                                                                     |
|--------------|-----------------|-----------------------------------------------------------------------------------------------------------------|
| 31 to 16     | DI_MSK_WE[15:0] | Enables write to DI_MSK[15:0].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable              |
| 15 to 0      | DI_MSK[15:0]    | Set the PORT15 DI_MSK pin value bit[15:0].<br>0b: Remove masking of the input data.<br>1b: Mask the input data. |

40.4.2.186 PORT15 Input/Output Enable Mask Register (PFC\_P15\_EN\_MSK)

This register controls masking of input/output enable for the PORT15 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 03F4h  
Initial Value: 0000\_FFFFh

Table 40.4-239 PFC\_P15\_EN\_MSK Register Contents

| Bit Position | Bit Name          | Description                                                                                                                        |
|--------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 16     | EN_MSK_WE [15:00] | Enables write to EN_MSK[15:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable                                |
| 15 to 0      | EN_MSK[15:00]     | Set the PORT15 EN_MSK pin bit[15:00] value.<br>0b: Remove masking of the input/output enable.<br>1b: Mask the input/output enable. |

40.4.2.187 PORT16 GPIO Output Value Control Register (PFC\_P16\_GPIO\_DO)

This register controls the output value of GPIO PORT16.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0400h  
Initial Value: 0000\_0000h

Table 40.4-240 PFC\_P16\_GPIO\_DO Register Contents

| Bit Position | Bit Name     | Description                                                                                      |
|--------------|--------------|--------------------------------------------------------------------------------------------------|
| 31, 30       | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                        |
| 29 to 16     | DO_WE[13:00] | Enables write to DO[13:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable  |
| 15, 14       | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                        |
| 13 to 0      | DO[13:00]    | Set the GPIO PORT16 bit[13:00] value.<br>0b: Output the low level.<br>1b: Output the high level. |

40.4.2.188 PORT16 GPIO Output Control Register (PFC\_P16\_GPIO\_OE)

This register controls whether GPIO PORT16 output is enabled or disabled.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0404h  
Initial Value: 0000\_0000h

Table 40.4-241 PFC\_P16\_GPIO\_OE Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31, 30       | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 29 to 16     | OE_WE[13:00] | Enables write to OE[13:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15, 14       | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 13 to 0      | OE[13:00]    | Control the output of GPIO PORT16 bit[13:00].<br>0b: Disable output.<br>1b: Enable output.      |

40.4.2.189 PORT16 GPIO Input Control Register (PFC\_P16\_GPIO\_IE)

This register controls whether GPIO PORT16 input is enabled or disabled.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0408h  
Initial Value: 0000\_0000h

Table 40.4-242 PFC\_P16\_GPIO\_IE Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31, 30       | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 29 to 16     | IE_WE[13:00] | Enables write to IE[13:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15, 14       | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 13 to 0      | IE[13:00]    | Control the input of GPIO PORT16 pin bit[13:00].<br>0b: Disable input.<br>1b: Enable input.     |

#### 40.4.2.190 PORT16 Function Select Register 0 (PFC\_P16\_PFSEL0)

This register controls function selection of the multi-purpose pin in PORT16.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 0410h

**Initial Value:** 0000\_0000h

#### 40.4.2.192 PORT16 Function Select Register 2 (PFC\_P16\_PFSEL2)

This register controls function selection of the multi-purpose pin in PORT16.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 0418h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30      | 29   | 28   | 27 | 26      | 25   | 24   | 23 | 22      | 21   | 20   | 19 | 18      | 17   | 16   |

**Remarks:** —: Setting prohibited

#### 40.4.2.193 PORT16 Function Select Register 3 (PFC\_P16\_PFSEL3)

This register controls function selection of the multi-purpose pin in PORT16.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 041Ch

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22      | 21   | 20   | 19 | 18      | 17   | 16   |

**Remarks:** —: Setting prohibited

40.4.2.194 PORT16 Input Value Monitor Register (PFC\_P16\_DI\_MON)

This register is a read-only register that monitors the input value of the PORT16 input pin (P16\_DI).

Writing is ignored.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0420h  
Initial Value: 0000\_xxxxh

|               |    |    |           |    |    |    |    |    |    |    |    |    |    |    |    |    |

Table 40.4-251 PFC\_P16\_DI\_MON Register Contents

| Bit Position | Bit Name  | Description                                     |
|--------------|-----------|-------------------------------------------------|
| 31 to 14     | —         | Reserved. These bits are read as 0b.            |
| 13 to 0      | DI[13:00] | The input value of PORT16 input pin bit[13:00]. |

#### 40.4.2.195 PORT16 Pull-Up/Down Control Register (PFC\_P16\_PUPD)

This register controls pulling up and down of the PORT16 pin.

**Access Size:** 32 bits

**Address(es):** <PFC\_S0\_base> + 0424h

**Initial Value:** 0555\_5555h

| Bit           | 31     | 30  | 29     | 28  | 27     | 26  | 25     | 24  | 23     | 22  | 21     | 20  | 19     | 18  | 17     | 16  |

| Bit Position | Bit Name   | Description                                                                                              |
|--------------|------------|----------------------------------------------------------------------------------------------------------|
| 31 to 28     | —          | Reserved. These bits are read as 0b. The write value should always be 0b.                                |
| 27 to 0      | DRV[13:00] | Control the PORT16 pin bit[13:00] I/O buffer drive strength.<br>00b: X1<br>01b: X2<br>10b: X4<br>11b: X6 |

40.4.2.197 PORT16 Slew-rate Control Register (PFC\_P16\_SR)

This register controls the slew-rate of the PORT16 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 042Ch  
Initial Value: 0000\_3FFFh

Table 40.4-254 PFC\_P16\_SR Register Contents

| Bit Position | Bit Name     | Description                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------|
| 31, 30       | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 29 to 16     | SR_WE[13:00] | Enables write to SR[13:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable |
| 15, 14       | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                       |
| 13 to 0      | SR[13:00]    | Set the PORT16 pin bit[13:00] SR value.<br>0b: Fast slew<br>1b: Slow slew                       |

40.4.2.198 PORT16 Input Data Mask Register (PFC\_P16\_DI\_MSK)

This register controls masking of input data of the PORT16 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0430h  
Initial Value: 0000\_3FFFh

Table 40.4-255 PFC\_P16\_DI\_MSK Register Contents

| Bit Position | Bit Name         | Description                                                                                                      |
|--------------|------------------|------------------------------------------------------------------------------------------------------------------|
| 31, 30       | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 29 to 16     | DI_MSK_WE[13:00] | Enables write to DI_MSK[13:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable              |
| 15, 14       | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 13 to 0      | DI_MSK[13:00]    | Set the PORT16 DI_MSK pin value bit[13:00].<br>0b: Remove masking of the input data.<br>1b: Mask the input data. |

40.4.2.199 PORT16 Input/Output Enable Mask Register (PFC\_P16\_EN\_MSK)

This register controls masking of input/output enable for the PORT16 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0434h  
Initial Value: 0000\_3FFFh

Table 40.4-256 PFC\_P16\_EN\_MSK Register Contents

| Bit Position | Bit Name          | Description                                                                                                                        |
|--------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 31, 30       | —                 | Reserved. These bits are read as 0b. The write value should always be 0b.                                                          |
| 29 to 16     | EN_MSK_WE [13:00] | Enables write to EN_MSK[13:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable                                |
| 15, 14       | —                 | Reserved. These bits are read as 0b. The write value should always be 0b.                                                          |
| 13 to 0      | EN_MSK[13:00]     | Set the PORT16 EN_MSK pin bit[13:00] value.<br>0b: Remove masking of the input/output enable.<br>1b: Mask the input/output enable. |

40.4.2.200 PORT17 GPIO Output Value Control Register (PFC\_P17\_GPIO\_DO)

This register controls the output value of GPIO PORT17.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0440h  
Initial Value: 0000\_0000h

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |         |

40.4.2.204 PORT17 Input Value Monitor Register (PFC\_P17\_DI\_MON)

This register is a read-only register that monitors the input value of the PORT17 input pin (P02\_DI).

Writing is ignored.

Immediately after reset, this register becomes 0000\_0000h.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0460h  
Initial Value: 0000\_000xh

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |      |

**Remarks:** —: Setting prohibited

40.4.2.214 PORT20 Input Value Monitor Register (PFC\_P20\_DI\_MON)

This register is a read-only register that monitors the input value of the PORT20 input pin (P02\_DI).

Writing is ignored.

Immediately after reset, this register becomes 0000\_0000h.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0520h  
Initial Value: 0000\_000xh

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |

| Bit Position | Bit Name         | Description                                                                                                      |
|--------------|------------------|------------------------------------------------------------------------------------------------------------------|
| 31 to 19     | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 18 to 16     | DI_MSK_WE[02:00] | Enables write to DI_MSK[02:00].<br>Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable              |
| 15 to 3      | —                | Reserved. These bits are read as 0b. The write value should always be 0b.                                        |
| 2 to 0       | DI_MSK[02:00]    | Set the PORT20 DI_MSK pin value bit[02:00].<br>0b: Remove masking of the input data.<br>1b: Mask the input data. |

40.4.2.217 PORT20 Input/Output Enable Mask Register (PFC\_P20\_EN\_MSK)

This register controls masking of input/output enable for the PORT20 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0534h  
Initial Value: 0000\_0007h

| 15 to 1      | —        | Reserved. These bits are read as 0b. The write value should always be 0b.                  |
| 0            | IE00     | Control the input of GPIO PORT21 pin bit 0.<br>0b: Disable input.<br>1b: Enable input.     |

40.4.2.221 PORT21 Input Value Monitor Register (PFC\_P21\_DI\_MON)

This register is a read-only register that monitors the input value of the PORT21 input pin (P02\_DI).

Writing is ignored.

Immediately after reset, this register becomes 0000\_0000h.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 0560h  
Initial Value: 0000\_000xh

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

40.4.2.223 PORT21 Slew-rate Control Register (PFC\_P21\_SR)

This register controls the slew-rate of the PORT21 pin.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 056Ch  
Initial Value: 0000\_0001h

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |         |

40.4.2.227 External Interrupt Signal Polarity Invert Control Register 0 (PFC\_EXTINT\_INV0)

This register controls whether the polarity of the external interrupt signal is inverted.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 05A0h  
Initial Value: 0000\_0000h

Table 40.4-288 PFC\_EXTINT\_INV0 Register Contents

| Bit Position | Bit Name      | Description                                                                                                                  |

| 15 to 0      | INV[15:00]    | Controls whether the polarity of the external interrupt terminal bit[15:00] is inverted.<br>0b: Not inverted<br>1b: Inverted |

40.4.2.228 External Interrupt Signal Polarity Invert Control Register 1 (PFC\_EXTINT\_INV1)

This register controls whether the polarity of the external interrupt signal is inverted.

Access Size: 32 bits  
Address(es): <PFC\_S0\_base> + 05A4h  
Initial Value: 0000\_0000h

Table 40.4-289 PFC\_EXTINT\_INV1 Register Contents

| 6 to 0       | MSK[38:32]    | Controls masking of the external interrupt terminal bit[38:32].<br>0b: Remove masking of the external interrupt signal.<br>1b: Mask the external interrupt signal. |

**Note:** Bits whose multiplexed function is other than external interrupt should always mask the external interrupt signal.

## 40.5 Functional Description

This section describes the functions of the PFC unit.

The prefix (PFC\_) of the register names is omitted in this and subsequent sections.

### 40.5.1 General-Purpose Input/Output Port (GPIO) Function

The PFC unit supports the general-purpose input/output port (GPIO) function.

When the multiplexed pin function in use is GPIO, the following register settings allow input/output control for the corresponding external pins.

The output level of the corresponding external pins can be changed by controlling the following registers.

- Pnn\_GPIO\_DO register: External pin output value control
- Pnn\_GPIO\_OE register: External pin output enable control

By controlling the following register, the input level of the corresponding external pins can be monitored via the Pnn\_DI\_MON register.

- Pnn\_GPIO\_IE register: External pin input enable control

Note: nn = 00 to 17, 20, 21

### 40.5.2 Multiplexed Pin Function Switching

The PFC unit is able to switch the multiplexed pin function for the external pins by the following register setting.

**Table 40.1-3** lists the correspondence between the external pins and the assigned multiplexed pin functions.

- Pnn\_PFSELx register: Multiplexed pin function switching

The PFC unit has the following registers to prevent propagation of glitches, which are generated when switching the multiplexed pin function by the Pnn\_PFSEL0 to 3 registers, to the external pins and internal propagation of glitches.

- Pnn\_DI\_MSK register: Forcibly masking the inputs from the external pins (IO buffer).
- Pnn\_EN\_MSK register: Forcibly masking the input/output enable for the external pins (IO buffer).

Note: nn = 00 to 17, 20  
x = 0 to 3

### 40.5.2.1 Pnn\_EN\_MSK (Input/Output Enable Masking) Register

The Pnn\_EN\_MSK register is used to prevent propagation of glitches, which are generated when switching the multiplexed pin function by the Pnn\_PFSEL0 to 3 registers (for multiplexed pin function switching), to the external pins.

Setting the Pnn\_EN\_MSK register for masking forcibly disables the output enable signal (Pnn\_OE\_N) and input enable signal (Pnn\_IE) for the I/O buffer of the corresponding external pins.

**Figure 40.5-1** shows an example of output waveforms of Pnn\_DO, Pnn\_OE\_N, and Pnn\_IE when switching the multiplexed pin function.

Figure 40.5-1 Example of Output Waveforms of Data and Enable Signals when Switching the Multiplexed Pin Function

### 40.5.2.2 Pnn\_DI\_MSK (Input Data Masking) Register

The Pnn\_DI\_MSK register is used to prevent internal propagation of glitches which are generated due to the effects of skew on Pnn\_OE\_N and Pnn\_IE when setting input/output enable masking described in **Section 40.5.2.1, Pnn\_EN\_MSK (Input/Output Enable Masking)**. Setting the Pnn\_DI\_MSK register for masking forcibly masks the signals to be supplied to the internal unit.

The value of Pnn\_PFX\_DI when masking input data is the same value as the initial value. The initial values of the pins are listed in **Section 40.3.1, List of Internal Pins**.

**Figure 40.5-2** shows an example of output waveforms of Pnn\_DO, Pnn\_OE\_N, and Pnn\_IE when switching the multiplexed pin function.

Figure 40.5-2 Example of Output Waveforms of Data when Switching Input/Output Enable Masking

### 40.5.3 Pin Function Control

The PFC unit is able to switch the pull-up/down, drive strength, and slew rate of the I/O buffer by using the following registers.

- Pnn\_PUPD register: Pull-up/down switching
- Pnn\_DRV register: Drive strength switching
- Pnn\_SR register: Slew rate switching

Note: nn = 00 to 17, 20, 21

### 40.5.4 CSRXD Input Pin Selection

The setting of the Pnn\_PFSELY register allows external pins CSRXDx and CSTXDx to switch the multiplexed pin function to the serial data input for the CSIx unit (CSRXDx). Switching the multiplexed pin function to the serial data input for the CSIx unit (CSRXDx) also requires setting the following registers in addition to changing the setting of the Pnn\_PFSELY register.

- RXDx of the CSRXD\_SEL register: Selection of the input for the CSIx unit (Select external pin CSRXDx or CSTXDx)

Note: nn = 03, 04  
x = 0 to 5, y = 0 to 3

### 40.5.5 External Interrupt Signal Active Sense Inversion Control

The PFC unit is able to control whether or not to invert the active sense of the external interrupt signal.

Target: Pins whose multiplexed function is INEXINTn.

Note: n = 0 to 38

When the external interrupt signal is active low, the active sense of this signal can be inverted by using this function. The active-high interrupt signal can be conveyed to the interrupt controller (GIC) in accord with the specification of the interrupt controller (GIC).

This can be controlled by the following register setting.

- EXTINT\_INVx register: External interrupt signal active sense control

Note: x = 0 to 2

### 40.5.6 External Interrupt Signal Masking Control

The PFC unit is able to control whether or not to mask the external interrupt signal.

This function is used to prevent glitches when switching the multiplexed pin function and false detection of interrupts due to switching of the setting for active sense inversion of the interrupt.

Target: Pins whose multiplexed function is INEXINTn

#### CAUTION

Bits whose multiplexed function is other than external interrupt should always mask the external interrupt signal.

This can be controlled by the following register setting.

- EXTINT\_MSKx register: External interrupt signal masking control

Note: n = 0 to 38  
x = 0 to 2

## 40.6 Operating Procedure

### 40.6.1 Procedure for Writing to the Registers

The 16 higher-order bits of the bank address switching register are write enable and the 16 lower-order bits are normal data registers, so changing only the value of the specified bits is possible without read-modify-write operation.

When changing the value, write 1 to the bit plus 16 of the bit to be changed.

Example: To set bit[0] to 1b, write 0001\_0001h. To set it to 0b, write 0001\_0000h. The value of bit[15:0] is not changed when 0000\_xxxxh is written. (x: Don't care)

- PORTnn GPIO output value control register (Pnn\_GPIO\_DO)
- PORTnn GPIO output control register (Pnn\_GPIO\_OE)
- PORTnn GPIO input control register (Pnn\_GPIO\_IE)
- PORTmm Function Select registers 0 to 3 (Pmm\_PFSEL0 to 3)
- PORTnn slew rate switching register (Pnn\_SR)
- CSRXD input pin switching register (CSRXD\_SEL)
- External interrupt signal active sense inversion control registers 0 to 2 (EXTINT\_INV0 to 2)
- External Interrupt Signal Mask Control registers 0 to 2 (EXTINT\_MSK0 to 2)
- PORTmm input data masking register (Pmm\_DI\_MSK)
- PORTmm input/output enable masking register (Pmm\_EN\_MSK)

When read, the 16 higher-order bits are always read as 0b.

The following registers have no enable function for writing.

- PORTnn Pull-Up/Down Control register (Pnn\_PUPD)
- PORTnn Drive Strength Control register (Pnn\_DRV)
- Dedicated Drive Strength Control register (PEX0\_DRV)

The following registers are read only and writing to these registers has no effect.

- PORTnn Input Value Monitor register (Pnn\_DI\_MON)

Note: nn = 00 to 17, 20, 21

mm = 00 to 17, 20

## 40.6.2 Initial Settings of Multiplexed Pins

### 40.6.2.1 Initial States of Pins

After release from the system reset, the individual pins are set as listed in **Table 40.6-1**.

Table 40.6-1 Settings after Release from the System Reset

| Setting Item                | Setting after Release from System Reset       |
|-----------------------------|-----------------------------------------------|
| Drive strength              | The setting depends on the pin.* <sup>1</sup> |
| Pull-up/pull-down           | The setting depends on the pin.* <sup>2</sup> |
| Multiplexed function        | GPIO                                          |
| Input data masking          | Enable (masking enabled)                      |
| Input/output enable masking | Enable (masking enabled)                      |
| Slew rate                   | Slow slew                                     |

Note 1. For the settings for each pin, see the description of Pnn\_DRV in **Section 40.4.2, Register Descriptions**.

Note 2. For the settings for each pin, see the description of Pnn\_PUPD in **Section 40.4.2, Register Descriptions**.  
nn = 00 to 17, 20, 21

**Figure 40.6-1** shows the states of the pins at that time.

Figure 40.6-1 GPIO Pin States after Release from Reset and Setting

#### 40.6.2.2 Procedure for Initial Settings of Pins

The following describes the procedure for controlling the pin functions and pin characteristics.

1. Set input data for masking (set the target bit of the Pnn\_DI\_MSK register of PFC).
2. Set input/output enable for masking (set the target bit of the Pnn\_EN\_MSK register of PFC).
3. Set pull-up or pull-down (set the target bit of the Pnn\_PUPD register of PFC).
4. Set the drive strength (set the target bit of the Pnn\_DRV register of PFC).
5. Select the multiplexed pin function (set the target bit of the Pnn\_PFSEL register of PFC).
6. Remove masking of input/output enable (set the target bit of the Pnn\_EN\_MSK register of PFC).
7. Remove masking of input data (set the target bit of the Pnn\_DI\_MSK register of PFC).

For the setting registers, see **Section 40.4.2, Register Descriptions** and **Section 40.5.2, Multiplexed Pin Function Switching**.

When switching the multiplexed pin function to the function other than GPIO, follow the procedure described in **Section 40.6.3, Multiplexed Function Switching Procedure**.

### 40.6.3 Multiplexed Function Switching Procedure

Since the 3-bit select signal is used for switching of the multiplexed pin function, glitches may be generated due to skew on the select signal. Therefore, the following procedure must be observed to prevent propagation of glitches when switching the multiplexed pin function.

#### CAUTION

When switching the multiplexed pin function, only do so while the function of the related unit is stopped. Furthermore, operation of the unit after switching the multiplexed pin function must only be started after reading the register of this unit which was most recently set (to secure the time until the setting is reflected in the external pin).

#### 40.6.3.1 Procedure for Switching Pins which Do Not Include External Interrupts (INEXINT0 to 38) as Multiplexed Function

1. Use the Pmm\_DI\_MSK register for setting to mask input data on the pins for multiplexed function switching.
2. Use the Pmm\_EN\_MSK register for setting to mask input/output enable for the pins for multiplexed function switching.
3. Use the Pmm\_PFSEL0 to 3 registers to switch the multiplexed function.
4. Use the Pmm\_EN\_MSK register for setting to remove masking of input/output enable.
5. Use the Pmm\_DI\_MSK register for setting to remove masking of input data.

Note: mm = 00 to 17, 20

#### 40.6.3.2 Procedure for Switching Pins which Include External Interrupts (INEXINT0 to 38) as Multiplexed Function

##### (1) Procedure for switching the multiplexed function other than external interrupt to external interrupt

1. Use the EXTINT\_INV0 to 2 registers to set whether or not to invert the active sense of the external interrupt signal.
2. Set the multiplexed function as external interrupt through the procedure described in **Section 40.6.3.1, Procedure for Switching Pins which Do Not Include External Interrupts (INEXINT0 to 38) as Multiplexed Function**.
3. Use the EXTINT\_MSK0 to 2 registers to remove masking of the external interrupt signal.

##### (2) Procedure for switching the multiplexed function from external interrupt to the function other than external interrupt

1. Use the EXTINT\_MSK0 to 2 registers for setting to mask the external interrupt signal on the pins for multiplexed function switching.
2. Set the multiplexed function through the procedure described in **Section 40.6.3.1, Procedure for Switching Pins which Do Not Include External Interrupts (INEXINT0 to 38) as Multiplexed Function**.

**(3) Procedure for switching the multiplexed function other than external interrupt to the function other than external interrupt**

1. Set the multiplexed function through the procedure in **Section 40.6.3.1, Procedure for Switching Pins which Do Not Include External Interrupts (INEXINT0 to 38) as Multiplexed Function.**

#### 40.6.4 CSRXD Input Pin Selection

Switching the multiplexed function to serial data input for the CSIx unit (CSRXDx) requires the following two steps.

- Set the multiplexed function to CSRXDx through the procedure described in **Section 40.6.3.1, Procedure for Switching Pins which Do Not Include External Interrupts (INEXINT0 to 38) as Multiplexed Function**.
- Use the CSRXD\_SEL register to select the corresponding pins.

The above two steps can be performed in any order.

Note: x = 0 to 5

Example setting: When changing the external pin CSRXD0 to the serial data input for CSI0

- Set the multiplexed function of external pin CSRXD0 to CSRXD0 through the procedure described in **Section 40.6.3.1, Procedure for Switching Pins which Do Not Include External Interrupts (INEXINT0 to 38) as Multiplexed Function**.
- Set the CSRXD\_SEL register to 0001\_0000h.

#### 40.6.5 Procedure for Switching the Active Sense of the External Interrupt Signal

Set whether or not to invert the active sense of the external interrupt signal as follows.

- When using an active-high signal as external interrupt signal:  
The setting is for non-inversion of the active sense.
- When using an active-low signal as external interrupt signal:  
The setting is for inversion of the active sense.

Furthermore, when switching the active sense of the signal while external interrupt is selected as the multiplexed function, the following procedure must be observed to prevent false detection of external interrupts.

1. Use the EXTINT\_MSK0 to 2 registers to mask the external interrupt on the target pins for active sense switching.
2. Use the EXTINT\_INV0 to 2 registers to set whether or not to invert the active sense of the external interrupt signal.
3. Use the EXTINT\_MSK0 to 2 registers to remove masking of the external interrupt on the target pins for active sense switching.

## 40.7 Usage Notes

- When setting the pin functions and pin characteristics, read the registers after writing to them and check that the values have been set before using the pins.
- For the pins for which the multiplexed function other than external interrupt is selected, always mask the external interrupt signal.
- For the MD4-MD7 pins, provide a mechanism for switching the high and low level for the input outside the LSI chip.

## Section 41 Display Control

This section describes the overview of the display control of this LSI.

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 41.1 Connection Configuration

The display control is composed of a display control unit (DCU) and an HDMI Tx interface (HDMI). **Figure 41.1-1** shows the internal connection configuration with the DCU and HDMI.

Figure 41.1-1 Internal Connection Configuration with DCU and HDMI

## 41.2 Display Control Unit (DCU)

This section describes the functions of the display control unit (DCU).

### 41.2.1 Functional Overview

The DCU is a control unit for reading display data from the external LPDDR4 based on the display output timing.

The HDMI display output is handled through the HDMI Tx interface.

### 41.2.2 Features

- Maximum display size
  - HDMI:  $1920 \times 1080 \text{ p} \times 60 \text{ fps}$
- Resolution conversion
  - Image frame: Reduction by linear interpolation
  - Graphics frame: Expansion by simple interpolation
- Picture compositing
  - The image frame is assigned as the background and the graphics frame is assigned as the foreground.
  - For a single HDMI display
    - Two display areas (DRAMs) are used for each of the image and graphics screens.
    - Two image frames can be combined at a specified level, after which a composite is output with the given alpha values.
  - For simultaneous display via the HDMI
    - One display area (DRAM) is used for each of the image and graphics screens.
    - A composite is output with the given alpha values.
- Image frame adjustment
  - Brightness and chroma
- Dedicated image adjustment for HDMI
  - Color gain, color conversion, and brightness offset

### 41.2.3 Operating Procedure

For the HDMI, an API for display in the HDMI device in combination with the DCU is defined. For details, refer to the ISP control software specification.

## 41.3 HDMI Tx Interface (HDMI)

This section describes the functions of the HDMI Tx interface.

### 41.3.1 Functional Overview

The HDMI handles display output that is conformant with the HDMI specification, version 1.4a and the DVI specification, version 1.0.

### 41.3.2 Features

**Table 41.3-1** lists the functions of the HDMI

Table 41.3-1 List of the Functions

| Block Name | Category            | Item                            | Specification                                                                              |
|------------|---------------------|---------------------------------|--------------------------------------------------------------------------------------------|
| LINK       | Image               | Resolution                      | 1280 × 720p<br>1920 × 1080p                                                                |
|            |                     | Output format                   | YUV 444, YUV422                                                                            |

|            | Audio               | Interface                       | I2S                                                                                        |
|            |                     | Number of channels              | 2 ch.                                                                                      |
|            |                     | Sampling frequency              | 32 kHz, 44.1 kHz, 48 kHz                                                                   |
|            |                     | Encoding method                 | LPCM (Linear PCM)                                                                          |
|            |                     | Number of quantization bits     | 16 bits, 24 bits                                                                           |
|            | Interrupt           |                                 | Hot plug detection (sink device detection)<br>VSYNC detection<br>Error detection interrupt |
| PHY        | Operating frequency |                                 | Up to 2.97 Gbps                                                                            |

The following functions are not supported.

- CEC, HDCP, HEAC

**Table 41.3-2** lists the image formats supported by the HDMI.

Table 41.3-2 List of the Supported Image Formats

| Image Size    | Frame Rate (Hz) |
|---------------|-----------------|
| 1280 × 720 p  | 60.000          |
| 1920 × 1080 p | 60.000          |

## Section 42 Trusted Secure IP

For the security functions, contact a Renesas Electronics sales representative.

## Section 43 A/D Converter (ADCA, ADCB)

This section describes the functions of the A/D converter units A and B (ADCA, ADCB).

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 43.1 Functional Overview

This LSI chip incorporates two 12-bit successive-approximation A/D converter units. Up to 12 channels of analog input are selectable for unit A and up to eight channels are selectable for unit B. The A/D converter units A and B operate independently.

- Number of units: 2
- Input channels: 12 (unit A) and 8 (unit B)
- Resolution: 12 bits
- Sampling rate: 600 kS/s
- Operating modes
  - Single scan
  - Continuous scan

## Section 44 Temperature Sensor (TSU)

This section describes the functions of the temperature sensor (TSU).

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 44.1 Functional Overview

This LSI has two channels, ch. 0 and ch. 1, of TSU.

The temperature in this LSI can be obtained by reading the digital values to which the temperature sensor outputs were converted by the A/D converters.

## Section 45 Clock Pulse Generator (CPG)

This section describes the functions of the clock pulse generator (CPG).

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 45.1 Functional Overview

The CPG includes a clock generation block, a reset generation block, and an APB IF block, and supplies clocks and resets to the respective units.

**Table 45.1-1** is an overview of the functions.

Table 45.1-1 Function Overview

| Item                                   | Specification                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Clock generation and control functions | <ul style="list-style-type: none"> <li>This function divides the external input clock (oscillator (OSC48M) 48 MHz) or the PLL output clock to generate the clock to be supplied to the respective unit.</li> <li>Six PLLs are installed. The roles of these PLLs are as follows.*1 <ul style="list-style-type: none"> <li>PLL1 (SSCG-PLL): For CA53</li> <li>PLL2 (SSCG-PLL): For SYSTEM BUS, ISP</li> <li>PLL3 (SSCG-PLL): For LPDDR4</li> <li>PLL4 (Fractional-PLL): For STG, ADC</li> <li>PLL6 (SSCG-PLL): For DRP-AI</li> <li>PLL7 (SSCG-PLL): For the display control</li> </ul> </li> <li>The PLL oscillation frequency setting, clock division ratio setting, and output clock selection can be set by registers.</li> <li>This function generates bus clock enable signals for individual units that require bus clock enable.</li> </ul> |
| Reset generation and control functions | <ul style="list-style-type: none"> <li>This function generates a reset from the respective reset factors. The types of resets are as follows. <ol style="list-style-type: none"> <li>System reset</li> <li>Software control reset (individual unit reset by setting CPG register)</li> </ol> </li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

Note 1. In this LSI, PLL1, PLL2, PLL4, PLL6, and PLL7 are for use with the ISP support package. Therefore, do not write to the target registers. In addition, the target registers of PLL3 should not be rewritten because changing the LPDDR4 operation frequency after startup is prohibited.

Some tables and figures of this section are color-coded as information of the power domain.

The color coding by power domain is shown in **Table 45.1-2**.

Table 45.1-2 Color Coding by Power Domain

| Power Domain | Description                                |
|--------------|--------------------------------------------|
| PD_AWO       | The power domain that is always powered on |
| PD_MEM       | The power domain of the LPDDR4 systems     |
| PD_VIDEO0    | The power domain of the VIDEO0 systems     |
| PD_VIDEO1    | The power domain of the VIDEO1 systems     |
| PD_RFX       | The power domain of the RAMB systems       |
| PD_DRPA      | The power domain of the DRA-AI systems     |
| PD_CA53      | The power domain of the CA53 systems       |

## 45.2 Pin Functions

**Table 45.2-1** lists the external pins of the CPG.

Table 45.2-1 List of External I/O Pins

| Pin Name | I/O    | Function                                   |
|----------|--------|--------------------------------------------|
| RSTN     | Input  | External system reset                      |
| GMCLK0   | Output | General-purpose output clock 0             |
| GMCLK1   | Output | General-purpose output clock 1             |
| AUPLLCLK | Input  | Audio master clock input (Max. 12.288 MHz) |
| AUMCLK   | Output | Audio master clock output (12 MHz)         |

**Note:** The external pins are connected through the external connection unit.

## 45.3 Clocks

### 45.3.1 Clock System Diagram

**Figure 45.3-1** shows a simplified clock system diagram.

### 45.3.2 List of Clock Signals

Table 45.3-1 is a list of clock signals.

Table 45.3-1 List of Clock Signals (1/4)

| Unit    | Signal Name      | Frequency [MHz]   | Initial Value [MHz] | Clock Source | Value after Reset | Description                                            |
|---------|------------------|-------------------|---------------------|--------------|-------------------|--------------------------------------------------------|
| PMC     | PMC_CORE_CLOCK   | 48                | 48                  | OSC48M       | ON                | PMC core clock                                         |
| CST     | CST_CS_CLK       | 400/200/100/50/48 | 200                 | SEL B        | ON                | CoreSight main clock                                   |
|         | CST_TS_CLK       | 48                | 48                  | OSC48M       | ON                | CST timestamp clock                                    |
|         | CST_TRACECLK     | 100/50/48         | 100                 | SEL E        | ON                | CST trace clock                                        |
|         | CST_SB_CLK       | 200/100/50/48     | 200                 | SEL D        | ON                | Clock for CST DebugAPB (system bus ↔ CoreSight)        |
|         | CST_AHB_CLK      | 48                | 48                  | OSC48M       | ON                | Clock for CST AHB (authentication circuit ↔ CoreSight) |
|         | CST_APB_CA53_CLK | 400/200/100/50/48 | 200                 | SEL B        | ON                | Clock for CST CA53_DebugAPB                            |
|         | CST_ATB_SB_CLK   | 200/100/50/48     | 200                 | SEL D        | ON                | System bus synchronization clock for CST ATB bus       |
|         | CST_TS_SB_CLK    | 200/100/50/48     | 200                 | SEL D        | ON                | Timestamp clock for CST system bus                     |
| GIC     | GIC_CLK          | 200/100/50/25/24  | 100                 | SEL B/2      | ON                | GIC common clock (for AXI and other I/Fs)              |

| DRP-AI   | DRPA_ARESETN     | TYPE-B               | A+14*DRPA_INITCLK          | A+7*DRPA_INITCLK                     | DRP-AI reset            |         |
| ICB      | ICB_PD_AWO_RST_N | TYPE-A               | —                          | —                                    | ICB AWO domain reset    |         |
|          | ICB_PD_MMC_RST_N | TYPE-A               | —                          | —                                    | ICB MEM domain reset    |         |
|          | ICB_PD_VD0_RST_N | TYPE-A               | —                          | —                                    | ICB VIDEO0 domain reset |         |
|          | ICB_PD_VD1_RST_N | TYPE-A               | —                          | —                                    | ICB VIDEO1 domain reset |         |
|          | ICB_PD_RFX_RST_N | TYPE-A               | —                          | —                                    | ICB RFX domain reset    |         |

**Note:** The definitions and supplementary explanations of reset control types "TYPE-A" and "TYPE-B" are shown below.

TYPE-A: A type which does not require clock supply at the time of a reset.

TYPE-B: A type which requires clock supply at the time of a reset.

For details of the reset control types, see **Section 45.6.2.4(1), Reset Control TYPE-A** and **Section 45.6.2.4(2), Reset Control TYPE-B**.

Schematic views of the procedures by the register settings are shown in **Figure 45.4-2** and **Figure 45.4-3**.

The numbers in the "Reg" waveforms in the figures are the steps of the register settings.

Note 1. A is a constant.

A: 729.17 ns (35 cycles at 48 MHz)

Note 2. The definitions of the minimum assertion period and de-assertion transmission period are shown in **Figure 45.4-2** and **Figure 45.4-3**.

When the reset is asserted by the CPG register, set the reset release after the minimum assertion period has elapsed.  
In addition, access the unit after at least "de-assertion delay of the target unit" has elapsed.

Note 3. For more information, contact a Renesas Electronics sales representative.

Figure 45.4-2 Minimum Assertion Period, Deassertion Delay Definition for Target Unit (TYPE-A)

Figure 45.4-3 Minimum Assertion Period, Deassertion Delay Definition for Target Unit (TYPE-B)

## 45.5 Register Description

For the base address of the register (<CPG\_S0\_base>), see the Address Map section.

### 45.5.1 List of Registers

The following table is a list of registers in this unit.

Table 45.5-1 List of Registers (1/4)

| Offset Address                                        | Register Name                               | Abbreviation       | Initial Value | Access Unit (bits) |
|-------------------------------------------------------|---------------------------------------------|--------------------|---------------|--------------------|
| SSCG PLL(PLL1-3,6,7) Control Registers 000h-0FFh      |                                             |                    |               |                    |
| 000h                                                  | PLL1 (SSCG) Standby Control Register        | CPG_PLL1_STBY      | 0000_0005h    | 32                 |
| 004h                                                  | PLL1 (SSCG) Output Clock Setting Register 1 | CPG_PLL1_CLK1      | 0000_14C2h    | 32                 |
| 008h                                                  | PLL1 (SSCG) Output Clock Setting Register 2 | CPG_PLL1_CLK2      | 0015_0801h    | 32                 |
| 00Ch                                                  | PLL1 (SSCG) Monitor Register                | CPG_PLL1_MON       | 0000_0011h    | 32                 |
| 010h                                                  | PLL2 (SSCG) Standby Control Register        | CPG_PLL2_STBY      | 0000_0005h    | 32                 |
| 014h                                                  | PLL2 (SSCG) Output Clock Setting Register 1 | CPG_PLL2_CLK1      | 0000_1903h    | 32                 |
| 018h                                                  | PLL2 (SSCG) Output Clock Setting Register 2 | CPG_PLL2_CLK2      | 000E_0E00h    | 32                 |
| 01Ch                                                  | PLL2 (SSCG) Monitor Register                | CPG_PLL2_MON       | 0000_0011h    | 32                 |
| 020h                                                  | PLL3 (SSCG) Standby Control Register        | CPG_PLL3_STBY      | 0000_0004h    | 32                 |
| 024h                                                  | PLL3 (SSCG) Output Clock Setting Register 1 | CPG_PLL3_CLK1      | 0000_1903h    | 32                 |

## 45.5.2 Register Descriptions

The function description of each register is given below.

### 45.5.2.1 PLLm Standby Control Register (CPG\_PLLm\_STBY) (m = 1, 2, 3, 6, 7)

This register controls the power saving mode, standby, and SSC ON/OFF of SSCG PLLm.

In this LSI, PLL1, PLL2, PLL4, PLL6, and PLL7 are for use with the ISP support package. Therefore, do not write to the target registers. In addition, the target registers of PLL3 should not be rewritten because changing the LPDDR4 operation frequency after startup is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0000h (m = 1)  
 <CPG\_S0\_base> + 0010h (m = 2)  
 <CPG\_S0\_base> + 0020h (m = 3)  
 <CPG\_S0\_base> + 0030h (m = 6)  
 <CPG\_S0\_base> + 0040h (m = 7)

**Initial Value:** 0000\_0005h (m = 1)  
 0000\_0005h (m = 2)  
 0000\_0004h (m = 3)  
 0000\_0000h (m = 6)  
 0000\_0004h (m = 7)

Table 45.5-3 Mode Setting Table

| Mode        |               | Field  |        |               |
|-------------|---------------|--------|--------|---------------|
|             |               | RESETB | SSC_EN | SSC_MODE[1:0] |
| Reset state |               | 0b     | —      | —             |
| SSC OFF     |               | 1b     | 0b     | —             |
| SSC ON      | Down spread   |        | 1b     | 00b           |
|             | Up spread     |        |        | 01b           |
|             | Center spread |        |        | 10b           |
| Prohibited  |               |        |        | 11b           |

**Note:** In the case of Up spread or Center spread, the setting exceeding the maximum frequency is prohibited.

### 45.5.2.2 PLLm Output Clock Setting Register 1 (CPG\_PLLm\_CLK1) (m = 1, 2, 3, 6, 7)

This register sets the K, M, P divided value of SSCG PLLm.

In this LSI, PLL1, PLL2, PLL4, PLL6, and PLL7 are for use with the ISP support package. Therefore, do not write to the target registers. In addition, the target registers of PLL3 should not be rewritten because changing the LPDDR4 operation frequency after startup is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0004h (m = 1)  
 <CPG\_S0\_base> + 0014h (m = 2)  
 <CPG\_S0\_base> + 0024h (m = 3)  
 <CPG\_S0\_base> + 0034h (m = 6)  
 <CPG\_S0\_base> + 0044h (m = 7)

**Initial Value:** 0000\_14C2h (m = 1)  
 0000\_1903h (m = 2)  
 0000\_1903h (m = 3)  
 0000\_1A42h (m = 6)  
 0000\_18C2h (m = 7)

Note 1. PLL Oscillation frequency (F<sub>FVCO</sub>) and output frequency (F<sub>FOUT</sub>) may be calculated with the following formula.

- Formula

$$F_{FVCO} = \frac{\left(m + \frac{k}{65536}\right) \times F_{Fin}}{p}$$

$$F_{FOUT} = \frac{\left(m + \frac{k}{65536}\right) \times F_{Fin}}{p \times 2^S} \times 3$$

- Restriction

F<sub>Fin</sub>: 48 MHz

6 MHz ≤ F<sub>FREF</sub> = F<sub>Fin</sub>/p ≤ 24 MHz

1600 MHz ≤ F<sub>FVCO</sub> ≤ 3200 MHz

Note 2. F<sub>FVCO</sub>, F<sub>FOUT</sub> of DIV\_K, DIV\_M, DIV\_P, DIV\_S\*3 should be set within the following PLL settable range. SSCG frequency modulation function not exceeding the MAX limit is available.

Table 45.5-5 Mode Setting Table (FFVCO)

| SSCG PLL | F <sub>FVCO</sub> Min | F <sub>FVCO</sub> Default Configuration | F <sub>FVCO</sub> Max |
|----------|-----------------------|-----------------------------------------|-----------------------|

Note 3. See 45.5.2.3, PLLm Output Clock Setting Register 2 (CPG\_PLLm\_CLK2) (m = 1, 2, 3, 6, 7) as DIV\_S ("S").

Note 4. When the setting is changed, the PLL reset is required.

### 45.5.2.3 PLLm Output Clock Setting Register 2 (CPG\_PLLm\_CLK2) (m = 1, 2, 3, 6, 7)

This register sets the divided value and SSC modulation value (MFR, MMR) of SSCG PLLm.

In this LSI, PLL1, PLL2, PLL4, PLL6, and PLL7 are for use with the ISP support package. Therefore, do not write to the target registers. In addition, the target registers of PLL3 should not be rewritten because changing the LPDDR4 operation frequency after startup is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0008h (m = 1)  
 <CPG\_S0\_base> + 0018h (m = 2)  
 <CPG\_S0\_base> + 0028h (m = 3)  
 <CPG\_S0\_base> + 0038h (m = 6)  
 <CPG\_S0\_base> + 0048h (m = 7)

**Initial Value:** 0015\_0801h (m = 1)  
 000E\_0E00h (m = 2)  
 000E\_0E00h (m = 3)  
 0015\_0A01h (m = 6)

Note 1. Modulation frequency (MF) and Modulation rate (pk-pk) (MR) can be calculated with the following formula.

- Formula

$$MF = \frac{(F_{Fin})}{p \times mfr \times (2^5)}$$

$$MR = \frac{mfr \times mrr}{m \times 2^6} \times 100[\%]$$

- Restriction

Ffin: 48 MHz

0000\_0000b ≤ MFR[7:0] ≤ 1111\_1111b

00\_0001b ≤ MRR[5:0] ≤ 11\_1111b

0 ≤ mrr ≤ mfr ≤ 512

Note 2. See **45.5.2.2, PLLm Output Clock Setting Register 1 (CPG\_PLLm\_CLK1) (m = 1, 2, 3, 6, 7)** as DIV\_M(M), DUV\_P(P).  
The initial values of PLL1, 2, 3, 6, and 7 register settings and output clocks are listed in **Table 45.5-8** and **Table 45.5-9**.

| PLL6 | Reset state     | 1260                                 | OFF | 35.71      | Down spread | 3.13                 |
| PLL7 | Reset state     | 1188                                 | ON  | 35.71      | Down spread | 3.31                 |

#### 45.5.2.4 PLLm Monitor Register (CPG\_PLLm\_MON) (m = 1, 2, 3, 6, 7)

This register is for monitoring the state of SSCG PLLm.

In this LSI, PLL1, PLL2, PLL4, PLL6, and PLL7 are for use with the ISP support package. Therefore, do not write to the target registers. In addition, the target registers of PLL3 should not be rewritten because changing the LPDDR4 operation frequency after startup is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 000Ch (m = 1)  
 <CPG\_S0\_base> + 001Ch (m = 2)  
 <CPG\_S0\_base> + 002Ch (m = 3)  
 <CPG\_S0\_base> + 003Ch (m = 6)  
 <CPG\_S0\_base> + 004Ch (m = 7)

**Initial Value:** 0000\_0011h (m = 1)  
 0000\_0011h (m = 2)  
 0000\_0000h (m = 3)  
 0000\_0000h (m = 6)  
 0000\_0000h (m = 7)

Note 1. PLL Oscillation frequency ( $F_{FVCO}$ ) and output frequency ( $F_{FOUT}$ ) can be calculated with the following formula.

- Formula

$$F_{FVCO} = \frac{\left(m + \frac{k}{65536}\right) \times F_{Fin}}{p}$$

$$F_{FOUT} = \frac{\left(m + \frac{k}{65536}\right) \times F_{Fin}}{p \times 2^s} \times 3$$

- Restriction

$F_{Fin}$ : 48 MHz

$6 \text{ MHz} \leq F_{FREF} = F_{Fin}/p \leq 24 \text{ MHz}$

$1600 \text{ MHz} \leq F_{FVCO} \leq 3200 \text{ MHz}$

Note 2.  $F_{FVCO}$ ,  $F_{FOUT}$  of DIV\_K, DIV\_M, DIV\_P, DIV\_S\*3 should be set within the following PLL settable range.

Table 45.5-13 Mode Setting Table ( $F_{FVCO}$ )

| SSCG PLL | $F_{FVCO}$ Min | $F_{FVCO}$ Default Configuration | $F_{FVCO}$ Max |
|----------|----------------|----------------------------------|----------------|
| PLL4     | 2304 MHz       | 2304 MHz                         | 2592 MHz       |

Table 45.5-14 Mode Setting Table ( $F_{FOUT}$ )

| SSCG PLL | $F_{FOUT}$ Min | $F_{FOUT}$ Default Configuration | $F_{FOUT}$ Max |
|----------|----------------|----------------------------------|----------------|
| PLL4     | 576 MHz        | 576 MHz                          | 648 MHz        |

Note 3. See **45.5.2.7, PLL4 Output Clock Setting Register 2 (CPG\_PLL4\_CLK2)** as DIV\_S ("S")

Note 4. When the setting is changed, the PLL reset is required.

### 45.5.2.7 PLL4 Output Clock Setting Register 2 (CPG\_PLL4\_CLK2)

This register sets the divided value of Fractional PLL4.

This register is for use with the ISP support package. Therefore, changing this register is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0108h

**Initial Value:** 0000\_0002h

### 45.5.2.10 PLL2 Clock Control Circuit Reset Register (CPG\_PLL2\_CCTRL\_RST)

This register resets the clock control circuit of PLL2.

This register is for use with the ISP support package. Therefore, changing this register is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0184h

**Initial Value:** 0000\_3EFFh

#### 45.5.2.11 PLL3 Clock Control Circuit Reset Register (CPG\_PLL3\_CCTRL\_RST)

This register resets the clock control circuit of PLL3.

This register is for use with the ISP support package. Therefore, changing this register is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0188h

### 45.5.2.12 PLL4 Clock Control Circuit Reset Register (CPG\_PLL4\_CCTRL\_RST)

This register resets the clock control circuit of PLL4.

This register is for use with the ISP support package. Therefore, changing this register is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 018Ch

**Initial Value:** 0000\_003Fh

### 45.5.2.13 PLL7 Clock Control Circuit Reset Register (CPG\_PLL7\_CCTRL\_RST)

This register resets the clock control circuit of PLL7.

This register is for use with the ISP support package. Therefore, changing this register is prohibited.

#### 45.5.2.14 CA53 Clock Division Ratio Setting Register (CPG\_CA53\_DDIV)

This register sets the division ratio of CA53 core clock (DIV A).

The source clock is PLL1 (996 MHz). This register may be switched dynamically.

This register is for use with the ISP support package. Therefore, changing this register is prohibited.

**Access Size:** 32 bits

#### NOTE

Even if there is no change in the set value, writing '1' to "\_WEN" located in the upper 16 bits of the register starts the clock switching control. Therefore, it is necessary to wait until the switching is completed when monitoring their status (CPG\_CLKSTATUS). (The clock stops temporarily when switching.)

### 45.5.2.15 System Division Ratio Setting Register (CPG\_SYS\_DDIV)

This register sets the division ratio of the system clock (DIV B, D, E).

The source clock is the clock divided by PLL2 (1600 MHz). This register may be switched dynamically.

This register is for use with the ISP support package. Therefore, changing this register is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0204h

**Initial Value:** 0000\_0001h

**45.5.2.22 SDI/EMM Clock Source Setting Register (CPG\_SDIEMM\_SSEL)**

For more information on this register, contact a Renesas Electronics sales representative.

**45.5.2.23 STG Clock Division Ratio Setting Register (CPG\_STG\_SDIV)**

For more information on this register, contact a Renesas Electronics sales representative.

**45.5.2.24 STG/CIF Clock Source Setting Register (CPG\_STGCIF\_SSEL)**

For more information on this register, contact a Renesas Electronics sales representative.

**45.5.2.25 Display Clock Division Ratio Setting Register 1 (CPG\_DISP\_SDIV1)**

For more information on this register, contact a Renesas Electronics sales representative.

**45.5.2.26 Display Clock Source Setting Register 1 (CPG\_DISP\_SSEL1)**

For more information on this register, contact a Renesas Electronics sales representative.

### 45.5.2.27 GMCLK Clock Division Ratio Setting Register (CPG\_GMCLK\_SDIV)

This register sets the division ratio of the GMCLK0 and 1 clocks.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 031Ch

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24       | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16       |

### 45.5.2.28 GMCLK Clock Source Setting Register (CPG\_GMCLK\_SSEL)

This register switches the source clock of GMCLK0 and 1.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0320h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24       | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16       |

### 45.5.2.29 UART\_REF Clock Division Ratio Setting Register (CPG\_URT\_RCLK\_SDIV)

This register sets the division ratio of the sourced clock of UART0 and 1.

This register is for use with the ISP support package. Therefore, changing this register is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0328h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18       | 17 | 16       |

### 45.5.2.30 UART\_REF Clock Source Setting Register (CPG\_URT\_RCLK\_SSEL)

This register switches the source clock of UART0 and 1.

This register is for use with the ISP support package. Therefore, changing this register is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 032Ch

**Initial Value:** 0000\_0000h

### 45.5.2.31 CSI\_REF Clock Source Setting Register (CPG\_CSI\_RCLK\_SSEL)

This register switches the source clock of CSI0 to 5.

This register is for use with the ISP support package. Therefore, the bits marked with \* should be written as '0'.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0330h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21           | 20          | 19           | 18           | 17           | 16          |

### 45.5.2.32 Clock ON/OFF Control Register 1 (CPG\_CLK\_ON1)

This register turns each unit clock on or off (AWO SYSTEM clock control).

This register is for use with the ISP support package. Therefore, the bits marked with \* should be written as '0'.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0400h

**Initial Value:** 0000\_FFEh

| Bit           | 31           | 30           | 29   | 28   | 27           | 26           | 25          | 24          | 23          | 22         | 21          | 20          | 19   | 18          | 17          | 16 |

## NOTES

- Clock on/off switching of ETH0\_CLK\_AXI and ETH0\_CLK\_CHI is reflected after register setting (synchronization with 48 MHz) and  $2 * \text{ETH0\_CLK\_CHI} + 4 * \text{ETH0\_CLK\_AXI}$ . On/off switching of other clocks is reflected after register setting (synchronization with 48 MHz) and synchronization to each clock (3 cycles later).
- The clock gating on/off timing depends on the frequency of the clock for synchronization.

### 45.5.2.36 Clock ON/OFF Control Register 5 (CPG\_CLK\_ON5)

This register turns each unit clock on or off (AWO GRP, CIF, and DCU clock control).

This register is for use with the ISP support package. Therefore, changing this register is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0410h

**Initial Value:** 0000\_0000h

## NOTES

- Clock on/off switching is reflected after register setting (synchronization with 48 MHz) and synchronization to each clock (3 cycles later).
- The clock gating on/off timing depends on the frequency of the clock for synchronization.

### 45.5.2.39 Clock ON/OFF Control Register 8 (CPG\_CLK\_ON8)

This register turns each unit clock on or off (AWO ADC and SYC clock control).

This register is for use with the ISP support package. Therefore, the bits marked with \* should be written as '0'.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 041Ch

**Initial Value:** 0000\_2000h

| Bit           | 31 | 30 | 29   | 28          | 27 | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19          | 18          | 17          | 16          |

## NOTES

- Clock on/off switching is reflected after register setting (synchronization with 48 MHz) and synchronization to each clock (3 cycles later).
- The clock gating on/off timing depends on the frequency of the clock for synchronization.

#### 45.5.2.40 Clock ON/OFF Control Register 9 (CPG\_CLK\_ON9)

This register turns each unit clock on or off (AWO Peripheral Group A clock control).

This register is for use with the ISP support package. Therefore, changing this register is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0420h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30 | 29 | 28          | 27          | 26          | 25         | 24         | 23         | 22         | 21         | 20         | 19 | 18 | 17 | 16         |

## NOTES

- Clock on/off switching is reflected after register setting (synchronization with 48 MHz) and synchronization to each clock (3 cycles later).
- The clock gating on/off timing depends on the frequency of the clock for synchronization.

#### 45.5.2.41 Clock ON/OFF Control Register 10 (CPG\_CLK\_ON10)

This register turns each unit clock on or off (AWO Peripheral Group B clock control).

This register is for use with the ISP support package. Therefore, the bits marked with \* should be written as '0'.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0424h

**Initial Value:** 0000\_0000h

## NOTES

- Clock on/off switching is reflected after register setting (synchronization with 48 MHz) and synchronization to each clock (3 cycles later).
- The clock gating on/off timing depends on the frequency of the clock for synchronization.

**45.5.2.44 Clock ON/OFF Control Register 13 (CPG\_CLK\_ON13)**

This register turns each unit clock on or off (AWO Peripheral Group E clock control).

This register is for use with the ISP support package. Therefore, changing this register is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0430h

**Initial Value:** 0000\_0000h

## NOTES

- Clock on/off switching is reflected after register setting (synchronization with 48 MHz) and synchronization to each clock (3 cycles later).
- The clock gating on/off timing depends on the frequency of the clock for synchronization.

### 45.5.2.45 Clock ON/OFF Control Register 14 (CPG\_CLK\_ON14)

This register turns each unit clock on or off (AWO Peripheral Group F clock control).

This register is for use with the ISP support package. Therefore, the bits marked with \* should be written as '0'.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0434h

**Initial Value:** 0000\_0000h

## NOTES

- Clock on/off switching is reflected after register setting (synchronization with 48 MHz) and synchronization to each clock (3 cycles later).
- The clock gating on/off timing depends on the frequency of the clock for synchronization.

#### 45.5.2.46 Clock ON/OFF Control Register 15 (CPG\_CLK\_ON15)

This register turns each unit clock on or off (AWO Peripheral Group G and H clock control).

This register is for use with the ISP support package. Therefore, the bits marked with \* should be written as '0'.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0438h

**Initial Value:** 0000\_0000h

## NOTES

- Clock on/off switching is reflected after register setting (synchronization with 48 MHz) and synchronization to each clock (3 cycles later).
- The clock gating on/off timing depends on the frequency of the clock for synchronization.

### 45.5.2.47 Clock ON/OFF Control Register 16 (CPG\_CLK\_ON16)

This register turns each unit clock on or off (ICB clock control 1).

Changing this register is prohibited because doing so causes system deadlock.

For details, see **Section 45.8.9, Register Control of CPG\_CLK\_ON16 and CPG\_CLK\_ON17**.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 043Ch

**Initial Value:** 0000\_FC1Dh

## NOTES

- ICB\_ACLK1 and ICB\_GIC\_CLK on/off switching is reflected after register setting (synchronization with 48 MHz) and 2 \* ICB\_GIC\_CLK + 4 \* ICB\_ACLK1. Other clock on/off switching is reflected after register setting (synchronization with 48 MHz) and synchronization to each clock (3 cycles later).
- The clock gating on/off timing depends on the frequency of the clock for synchronization.

**45.5.2.48 Clock ON/OFF Control Register 17 (CPG\_CLK\_ON17)**

This register turns each unit clock on or off (ICB clock control 2).

This register is for use with the ISP support package. Therefore, changing this register is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0440h

**Initial Value:** 0000\_0001h

## NOTES

- Clock on/off switching is reflected after register setting (synchronization with 48 MHz) and synchronization to each clock (3 cycles later).
- The clock gating on/off timing depends on the frequency of the clock for synchronization.

### 45.5.2.50 Clock ON/OFF Control Register 19 (CPG\_CLK\_ON19)

This register turns each unit clock on or off (CA53 system PD\_CA53 clock control).

This register is for use with the ISP support package. Therefore, changing this register is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0448h

**Initial Value:** 0000\_003Fh

| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21         | 20         | 19         | 18         | 17         | 16         |

## NOTES

- CA53\_CLK on/off switching is reflected after register setting (synchronization with 48 MHz) and 10\*CA53\_CLK. Other clock on/off switching is reflected after register setting (synchronization with 48 MHz) and synchronization to each clock (3 cycles later).
- The clock gating on/off timing depends on the frequency of the clock for synchronization.

### 45.5.2.51 Clock ON/OFF Control Register 20 (CPG\_CLK\_ON20)

This register turns each unit clock on or off (DRP-AI system PD\_DRPA clock control).

This register is for use with the ISP support package. Therefore, changing this register is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 044Ch

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18         | 17         | 16         |

| 10 to 8      | —          | Reserved. When read, the value read is undefined.                                                           |
| 7, 6         | —          | Reserved. These bits are read as 0b.                                                                        |
| 5, 4         | —          | Reserved. When read, the value read is undefined.                                                           |
| 3, 2         | —          | Reserved. These bits are read as 0b.                                                                        |
| 1            | —          | Reserved. When read, the value read is undefined.                                                           |
| 0            | CLK0_ON    | RAMB_ACLK[3:0] switches ON/OFF.<br>0b: Clock OFF (Clock stopped state)<br>1b: Clock ON (Clock supply state) |

#### NOTES

- Clock on/off switching is reflected after register setting (synchronization with 48 MHz) and synchronization to each clock (3 cycles later).
- The clock gating on/off timing depends on the frequency of the clock for synchronization.

### 45.5.2.53 Clock ON/OFF Control Register 24 (CPG\_CLK\_ON24)

This register turns each unit clock on or off (ISP, GPA, and STG system PD\_VIDEO0 clock control).

This register is for use with the ISP support package. Therefore, changing this register is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 045Ch

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21         | 20         | 19         | 18         | 17         | 16         |

## NOTES

- Clock on/off switching is reflected after register setting (synchronization with 48 MHz) and synchronization to each clock (3 cycles later).
- The clock gating on/off timing depends on the frequency of the clock for synchronization.

#### 45.5.2.54 Clock ON/OFF Control Register 25 (CPG\_CLK\_ON25)

This register turns each unit clock on or off (ISP, GPA, and MTD system PD\_VIDEO1 clock control).

This register is for use with the ISP support package. Therefore, changing this register is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0460h

**Initial Value:** 0000\_0000h

## NOTES

- VCD\_ACLK, VCD\_PCLK on/off switching is reflected after register setting (synchronization with 48 MHz) and  $2 * VCD\_PCLK + 4 * VCD\_ACLK$ . Other clock on/off switching is reflected after register setting (synchronization with 48 MHz) and synchronization to each clock (3 cycles later).
- The clock gating on/off timing depends on the frequency of the clock for synchronization.

**45.5.2.56 Clock ON/OFF Control Register 27 (CPG\_CLK\_ON27)**

This register turns each unit clock on or off (LPDDR4 system PD\_MEM clock control).

This register should not be rewritten because changing the LPDDR4 operation frequency after startup is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0468h

**Initial Value:** 0000\_0000h

| 1            | CLK1_ON    | MMC_ACLK switches ON/OFF.<br>0b: Clock OFF (Clock stopped state)<br>1b: Clock ON (Clock supply state)               |
| 0            | CLK0_ON    | MMC_CORE_DDRC_CORE_CLK switches ON/OFF.<br>0b: Clock OFF (Clock stopped state)<br>1b: Clock ON (Clock supply state) |

NOTES

---

- Clock on/off switching is reflected after register setting (synchronization with 48 MHz) and synchronization to each clock (3 cycles later).
  - The clock gating on/off timing depends on the frequency of the clock for synchronization.
-

### 45.5.257 WDT Reset Range Select Register (CPG\_WDT\_RST)

This register sets the reset range on reset occurrence.

This register is for use with the ISP support package. Therefore, the bits marked with \* should be written as '0'.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0500h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17                   | 16                  |

Table 45.5-57 CPG\_WDT\_RST Register Contents

| Bit Position | Bit Name    | Description                                                                                                                                                                                                   |
|--------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 19     | —           | Reserved. These bits are read as 0b.                                                                                                                                                                          |
| 18           | —           | Reserved. This bit is read as 0b. The write value should always be 0b.                                                                                                                                        |
| 17*          | WDTRST1_WEN | Enables write for WDTRST1 (bit 1). Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable                                                                                                           |
| 16           | WDTRST0_WEN | Enables write for WDTRST0 (bit 0). Write only. Read as 0b.<br>0b: Write disable<br>1b: Write enable                                                                                                           |
| 15 to 3      | —           | Reserved. These bits are read as 0b.                                                                                                                                                                          |
| 2            | —           | Reserved. When read, the value read is undefined.                                                                                                                                                             |
| 1            | WDTRST1     | Select the setting of the generated reset to system reset 2 or WDT CA53 Warm reset (Core 1).<br><i>Note:</i> WDT CA53 Warm reset (Core 1) prohibited.<br>0b: System reset<br>1b: WDT CA53 Warm reset (Core 1) |
| 0            | WDTRST0     | Select the setting of the generated reset to system reset 2 or WDT CA53 Warm reset (Core 0).<br><i>Note:</i> WDT CA53 Warm reset (Core 0) prohibited.<br>0b: System reset<br>1b: WDT CA53 Warm reset (Core 0) |

#### NOTE

A warm reset should follow the procedure (e.g. termination the bus transaction). A reset which is generated due to a WDT timeout occurs at an unexpected timing (e.g. software runaway). For this reason, if a WDT timeout reset occurs without software interaction, the setting for a warm reset is prohibited because warm booting may not be possible.

### 45.5.2.58 Reset Mask Register (CPG\_RST\_MSK)

This register masks the CA53 warm reset.

This register is for use with the ISP support package. Therefore, changing this register is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0504h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19          | 18          | 17           | 16           |

### 45.5.2.59 Reset Control Register 1 (CPG\_RST1)

This register controls each unit reset (AWO system reset control).

This register is for use with the ISP support package. Therefore, the bits marked with \* should be written as '0'.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0600h

**Initial Value:** 0000\_FFEh

| Bit           | 31   | 30              | 29              | 28              | 27   | 26              | 25             | 24             | 23             | 22             | 21            | 20   | 19   | 18             | 17             | 16 |

### 45.5.2.62 Reset Control Register 4 (CPG\_RST4)

This register controls each unit reset (AWO GRP, DCU, CIF, and HDMI reset control).

This register is for use with the ISP support package. Therefore, changing this register is prohibited.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 060Ch

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23   | 22   | 21            | 20            | 19            | 18            | 17            | 16   |

### 45.5.2.63 Reset Control Register 5 (CPG\_RST5)

This register controls each unit reset (AWO AUI, ISP, ADC, and SYC reset control)

This register is for use with the ISP support package. Therefore, the bits marked with \* should be written as '0'.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0610h

**Initial Value:** 0000\_0400h

| Bit           | 31 | 30 | 29 | 28 | 27 | 26   | 25            | 24   | 23   | 22   | 21             | 20             | 19 | 18             | 17   | 16             |

#### 45.5.2.64 Reset Control Register 6 (CPG\_RST6)

This register controls each unit reset (AWO Peripheral reset control).

This register is for use with the ISP support package. Therefore, the bits marked with \* should be written as '0'.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0614h

**Initial Value:** 0000\_3000h

| Bit           | 31 | 30   | 29             | 28             | 27 | 26              | 25             | 24             | 23            | 22             | 21             | 20             | 19             | 18            | 17            | 16             |

### 45.5.2.73 CPG Power Domain Reset Control Register (CPG\_PD\_RST)

This register controls each power domain reset of the CPG module.

This register is for use with the ISP support package. Therefore, the bits marked with \* should be written as '0'.

**Access Size:** 32 bits

**Address(es):** <CPG\_S0\_base> + 0800h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20               | 19                | 18                | 17               | 16              |

## 45.6 Functional Description

### 45.6.1 Clock Generation and Control Function

#### 45.6.1.1 SSCG PLL Control, Setting, and Monitoring

The SSCG PLL is controlled by the internal registers of the CPG.

Also, the states of the PLLs can be monitored by the output signals and internal registers of the CPG.

The SSCG PLL is for use with the ISP support package, so changing the setting is prohibited.

#### 45.6.1.2 Fractional PLL Control, Setting, and Monitoring

The fractional PLL (FRAC PLL) is controlled by the internal registers of the CPG.

Also, the states of the PLLs can be monitored by the output signals and internal registers of the CPG.

The fractional (FRAC) PLL is for use with the ISP support package, so changing the setting is prohibited.

#### 45.6.1.3 Clock Dividers and Selectors

The CPG uses several dividers and selectors to supply the clock signal according to the specification of a given unit.

A divider and selector can be divided into two types: a type which can be switched without stopping the clock signal for the unit (dynamic switching) and a type which requires switching after stopping the clock signal for the unit.

The types of divider and selector are as follows.

- Fixed divider
- Dynamic switching variable divider (decimation type)
- Dynamic switching variable divider (Duty50 type)
- Dynamic switching selector
- Static switching variable divider
- Static switching selector

For the connection specifications of the respective dividers, selectors, and PLLs, see **Section 45.3.1, Clock System Diagram**.

### (1) Fixed Divider

A divider which provides a fixed division value. It is connected between the output of the PLL and the variable divider. The division value is selectable from 1/2, 1/3, 1/4, 1/8, 1/16, and 1/24.

**Figure 45.6-1** is an example of connection of the 1/2 fixed divider.

Figure 45.6-1 Example of Connection of the Fixed Divider

**Figure 45.6-2** is a timing chart of various fixed dividers. The 1/2 fixed divider has two types, decimation type and Duty50 type.

Figure 45.6-2 Timing Chart of the Fixed Dividers

### (2) Dynamic Switching Variable Divider (Decimation Type)

A divider which allows switching of the clock signal without generating glitches when changing the division setting.

This divider can switch the clock signal without stopping the clock supply to a unit.

It generates a clock signal by decimating the source oscillation clock.

The division value is 1/1, 1/2, 1/3, 1/4, 1/6, 1/8, 1/12, 1/16, or 1/24 and the division value differs with a unit to be connected.

Clock switching requires a fixed time in order to prevent generation of glitches at the time of clock switching.

Whether switching is in progress can be monitored.

**Figure 45.6-3** is a schematic view of the allocation of the divider and **Figure 45.6-4** and **Figure 45.6-5** show the timing charts.

Figure 45.6-3 Schematic View of the Allocation of the Dynamic Switching Variable Divider (Decimation Type)

Figure 45.6-4 Timing Chart of the Dynamic Switching Variable Divider (Decimation Type)

Figure 45.6-5 Timing Chart of Clock Switching of the Dynamic Switching Variable Divider (Decimation Type)

(3) Dynamic Switching Variable Divider (Duty50 Type)

A divider which allows switching of the clock signal without generating glitches when changing the division setting. This divider can switch the clock signal without stopping the clock supply to a unit. It generates a clock signal of duty 50%. The division value is 1/1, 1/2, 1/4, 1/8, 1/16, or 1/32 and the division value differs with a unit to be connected. Clock switching requires a fixed time in order to prevent generation of glitches at the time of clock switching. Whether switching is in progress can be monitored.

Figure 45.6-6 is a schematic view of the allocation of the divider and Figure 45.6-7 and Figure 45.6-8 show the timing charts.

Figure 45.6-6 Schematic View of the Allocation of the Dynamic Switching Variable Divider (Duty50 Type)

Figure 45.6-7 Timing Chart of the Dynamic Switching Variable Divider (Duty50 Type)

Figure 45.6-8 Timing Chart of Clock Switching of the Dynamic Switching Variable Divider (Duty50 Type)

#### (4) Dynamic Switching Selector

A selector which allows changing the selection of the clock signal without generating glitches when changing the clock selection.

This selector can switch the clock signal without stopping the clock supply to a unit.

Clock switching requires a fixed time in order to prevent generation of glitches at the time of clock switching.

Whether switching is in progress can be monitored.

When switching the clock signal, make sure that the input clock signals of the selector are enabled.

Switching the clock signal while either of the input clock signals is stopped is prohibited.

**Figure 45.6-9** is a schematic view of the allocation of the selector and **Figure 45.6-10** shows the timing chart.

Figure 45.6-9 Schematic View of the Allocation of the Dynamic Switching Selector

Figure 45.6-10 Timing Chart of Clock Switching of the Dynamic Switching Selector

**Table 45.6-1** lists the related register.

Regarding the setting for switching, see the subsequent sections.

Table 45.6-1 List of the Divider and Selector Switching Monitoring Register

| Register Name                    | Abbreviation     | Function                                               |
|----------------------------------|------------------|--------------------------------------------------------|
| Clock status monitoring register | CPG_CLKSTATUS1,2 | Monitoring clock switching of the divider and selector |

### (5) Static Switching Variable Divider (Decimation Type, Duty50 Type, OtherDuty50 Type)

A glitch is generated as the division setting is immediately reflected in the clock output.

Accordingly, changing the setting requires stopping the clock supply to a unit.

Monitoring is not used because the setting is immediately reflected in the output.

There are three types of divider available: clock decimation type, Duty50 type which outputs a clock signal of duty 50%, and OtherDuty50 type which outputs a clock signal whose width at high level is shorter than the width at low level for one pulse at the time of odd-number division.

**Figure 45.6-11** is a schematic view of the allocation of the divider and **Figure 45.6-12** shows the timing chart.

Figure 45.6-11 Schematic View of the Allocation of the Static Switching Variable Divider

Figure 45.6-12 Timing Chart of Clock Switching of the Static Switching Variable Divider

(6) Static Switching Selector

A glitch is generated as the change to the clock selection setting is immediately reflected in the clock output. Accordingly, changing the setting requires stopping the clock supply to a unit. Monitoring is not used because the setting is immediately reflected in the output.

Figure 45.6-13 is a schematic view of the allocation of the selector and Figure 45.6-14 shows the timing chart.

Figure 45.6-13 Schematic View of the Allocation of the Static Switching Selector

Figure 45.6-14 Timing Chart of Clock Switching of the Static Switching Selector

#### 45.6.1.4 CA53 Control System

An independent system dedicated for Arm Cortex-A53 (CA53).

A clock frequency of 996 MHz is generated by PLL1 based on 48 MHz input externally to the CPG, and it is divided by the divider (DIV A) and then supplied to CA53. A schematic view of the allocation with PLL1 is as shown in **Figure 45.6-15**. For the overall block diagram of the CA53 control system, see **Section 45.3.1, Clock System Diagram**.

This system is for use with the ISP support package, so changing the setting is prohibited.

Figure 45.6-15 Block Diagram of the CA53 Control System (PLL1 Peripheral)

#### 45.6.1.5 System Bus/Storage/ISP Control System

A clock frequency of 1600 MHz is generated by PLL2 based on 48 MHz input externally to the CPG or the frequency-divided clock and 48 MHz and the clock signal which is frequency divided by a given divider is supplied to a given unit. For some units, the clock signal is supplied by switching the output clock from PLL2 and 48 MHz.

Also, PLL6 is provided for use in the supply of DCLK (DRPA\_DCLK) for DRP-AI and it generates 1260 MHz.

For the block diagram of the system bus control system, storage control system, ISP (video 0) control system, and ISP (video 1) control system, see **Section 45.3.1, Clock System Diagram**.

The system bus and ISP control systems are for use with the ISP support package, so changing the setting is prohibited.

#### (1) Storage Control System

The storage control clocks comprise a fixed clock signal.

For clock switching, the selector SEL SDI0 or SEL EMM is used.

SEL SDI0 and SEL EMM are set in common by using the register described in **Section 45.5.2.22, SDI/EMM Clock Source Setting Register (CPG\_SDIEMM\_SSEL)** and can switch 200 MHz and 48 MHz. Since these selectors are for static switching, be sure to switch the clock supply to the target unit off before making the register settings.

**Table 45.6-2** lists the available output frequencies for SEL SDI0. For the setting procedures for SEL SDI0/SEL EMM, see **Section 45.5.2.22, SDI/EMM Clock Source Setting Register (CPG\_SDIEMM\_SSEL)**.

Table 45.6-2 List of SDI0\_CCLK and EMM\_CCLK Output Frequency Settings

| Register Setting                 | Output Frequency |
|----------------------------------|------------------|
| SELSDI_SET<br>(SEL SDI0 Setting) | SDI0_CCLK        |
| 0                                | 48 MHz           |
| 1                                | 200 MHz          |

**Table 45.6-3** lists the related registers.

Table 45.6-3 List of the SEL SDI0 and SEL EMM Setting Register

| Register Name                           | Abbreviation    | Function                     |
|-----------------------------------------|-----------------|------------------------------|
| Clock source setting (SDI/EMM) register | CPG_SDIEMM_SSEL | SDI0/1 and EMM clock setting |

#### 45.6.1.6 LPDDR4 Control System

An independent system dedicated for LPDDR4, MMC, and DDI.

A clock frequency of 1600 to 1200 MHz is generated by PLL3 based on 48 MHz input externally to the CPG, and it is divided by the divider (DIV X) and then supplied to LPDDR4.

Since changing the operating frequency of LPDDR4 after startup is prohibited, do not change the setting.

A schematic view of the allocation with PLL3 is as shown in **Figure 45.6-16**. For the overall block diagram of the LPDDR4 control system, see **Section 45.3.1, Clock System Diagram**.

Figure 45.6-16 Block Diagram of the LPDDR4 Control System (PLL3 Peripheral)

#### 45.6.1.7 STG Control System

A clock frequency which is generated by PLL4 based on 24 MHz and 48MHz obtained by dividing 48 MHz input externally to the CPG is switched by the selector (SEL STG0) and then supplied to STG.

A reference clock for PLLs is supplied to an external CMOS image sensor via STG.

This system is for use with the ISP support package, so changing the setting is prohibited.

For the block diagram of the STG control system, see **Section 45.3.1, Clock System Diagram**.

#### 45.6.1.8 Display Control System

A clock signal is generated for the display control units, DCU, and HDMI.

This system is for use with the ISP support package, so changing the setting is prohibited.

For the block diagram of the display control system, see **Section 45.3.1, Clock System Diagram**.

#### 45.6.1.9 General-Purpose Clock Control System

For the general-purpose clock (GMCLK0/1), a clock source is selected from the following by the selector (SEL T/U) and a clock signal obtained by frequency division by the divider (DIV T/U) is output.

- Reference clock 48 MHz
- 100 MHz
- PLL4\_SELCK
- DISPCLK (PLL7)

For the block diagram of the general-purpose clock control system, see **Section 45.3.1, Clock System Diagram**.

### (1) About the Clock Setting

SEL T/U and DIV T/U are the selector and divider for static switching. Be sure to switch the clock supply to the target unit off before making the register settings.

To provide flexibility as a general-purpose clock, the division ratio settings for DIV T/U are available in 13 steps.

**Table 45.6-4** and **Table 45.6-5** list the available frequency division settings and output frequencies.

For the setting procedures for SEL T/U and DIV T/U, see **Section 45.5.2.27, GMCLK Clock Division Ratio Setting Register (CPG\_GMCLK\_SDIV)** and **Section 45.5.2.28, GMCLK Clock Source Setting Register (CPG\_GMCLK\_SSEL)**.

Table 45.6-4 List of SEL T/U Output Clock Settings

| SELT_SET<br>SELU_SET | SEL T<br>SEL U |
|----------------------|----------------|
| 00b                  | 48 MHz         |
| 01b                  | 100 MHz        |
| 10b                  | PL4_SELCK      |
| 11b                  | DISPCLK (PLL7) |

| 8h                   | SEL T(U)/20        |
| 9h                   | SEL T(U)/24        |
| Ah                   | SEL T(U)/32        |
| Bh                   | SEL T(U)/40        |
| Ch                   | SEL T(U)/48        |
| Other than the above | Setting prohibited |

**Table 45.6-6** lists the related registers.

Table 45.6-6 List of the General-Purpose Clock Control System Setting Registers

| Register Name                                 | Abbreviation   | Function                       |
|-----------------------------------------------|----------------|--------------------------------|
| Clock division ratio setting (GMCLK) register | CPG_GMCLK_SDIV | DIV T/U division ratio setting |
| Clock source setting (GMCLK) register         | CPG_GMCLK_SSEL | SEL T/U output clock setting   |

#### 45.6.1.10 ADC Clock

The ADC clock is configured to supply the fixed clock signal produced by frequency division of 48 MHz by 4 and to select and supply the clock signal produced by frequency division of the reference clock 48 MHz.

The ADC clock is for use with the ISP support package, so changing the settings is prohibited.

For the block diagram, see **Section 45.3.1, Clock System Diagram**.

#### 45.6.1.11 CPU Peripheral Control System

There are the TIM (32 ch.), IIC (4 ch.), WDT (2 ch.), PWM (16 ch.), CSI (6 ch.), and UART (2 ch.) as CPU peripheral units and each unit consists of eight groups from group A to H.

**Table 45.6-7** shows the group configuration.

Table 45.6-7 Group Configuration

| Group   | Unit         |
|---------|--------------|
| Group A | TIM0 to TIM7 |
|         | IIC[1:0]     |
| Group B | TIM[15:8]    |
|         | IIC[3:2]     |
| Group C | TIM[23:16]   |
|         | WDT[1:0]     |
| Group D | TIM[31:24]   |
| Group E | PWM[7:0]     |
| Group F | PWM[15:8]    |
| Group G | CSI[3:0]     |
|         | UART[1:0]    |
| Group H | CSI[5:4]     |

The configuration block diagrams of the respective groups are shown on the following pages.

**(1) Group A/B**

Groups A and B consist of eight TIMs and two IICs, respectively.

Figure 45.6-17 shows the block diagram.

Figure 45.6-17 Block Diagram of Groups A and B

**(2) Group C/D**

Group C consists of eight TIMs and two WDTs and group D consists of eight TIMs.

**Figure 45.6-18** shows the block diagram.

Figure 45.6-18 Block Diagram of Groups C and D

**(3) Group E/F**

Groups E and F consist of eight PWMs, respectively.

**Figure 45.6-19** shows the block diagram.

Figure 45.6-19 Block Diagram of Groups E and F

**(4) Group G/H**

Group G consists of four CSIs and two UARTs and group H consists of two CSIs.

**Figure 45.6-20** shows the block diagram.

Figure 45.6-20 Block Diagram of Groups G and H

### (5) About the UART Master Clock Setting

The clock signal produced by frequency division of the reference clock 48 MHz and PLL4 by the divider (DIV W) is supplied as a clock for communications.

The UART is already used with the ISP support package, so do not change the setting.

### (6) About the CSI Frequency Division Setting

The reference clock 48 MHz and 24MHz are selected by the selector (SEL CSI0 to 5) and supplied to a given CSI.

SEL CSI is the selector for static switching. Be sure to switch the clock supply to the target unit off before making the register settings.

Additionally, be sure to set CSI\_CLK to supply the frequency no greater than PCLK/2 (CPERI\_GRP\_PCLK/2, CPERI\_GRP\_PCLK/2).

PCLK is supplied from the output clock CPG\_SPCLK (100/50/48 MHz) set by DIV E/SEL E.

**Table 45.6-8** lists the SEL CSI selector settings.

Table 45.6-8 List of SEL CSI Output Clock Settings

| SEL CSIn (n = 0 to 5) | Output Clock |
|-----------------------|--------------|
| 0                     | 24 MHz       |
| 1                     | 48 MHz       |

#### 45.6.1.12 Unit Clock On/Off Control

The clocks for the respective units can be switched on and off.

**Table 45.6-9** lists the related registers.

Table 45.6-9 List of Clock On/Off Setting Registers

| Register Name                 | Abbreviation      | Function                  |
|-------------------------------|-------------------|---------------------------|
| Clock ON/OFF control register | CPG_CLK_ON1 to 27 | Unit clock on/off setting |

## 45.6.2 Reset Generation and Control Function

### 45.6.2.1 List of Resets

**Table 45.6-10** lists the resets of this LSI chip.

Table 45.6-10 List of Resets

| No.<br>*1 | Reset Name             | Reset Application<br>Range | Source                                          | Description                                                                                                    |
|-----------|------------------------|----------------------------|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| 1         | System reset           | Overall chip*2             | RSTN = L                                        | System reset by the external pin RSTN<br>(generated when the external pin RSTN = L)                            |
|           |                        |                            | WDT_RST_N[n] = L (n: 0, 1)*3                    | System reset by the timeout of WDT<br>(generated when WDT_RST_N[n] = L)                                        |
| 2         | Software control reset | Reset per unit             | The given reset control bit of CPG_RST1-15 is 0 | Reset per unit by the CPG register setting<br>(generated when the given reset control bit of CPG_RST1-15 is 0) |

Note 1. No. 1 to 3 are resets by hardware control of the CPG.

Note 2. RTC and PWC are excluded.

Note 3. This is the case when the register CPG\_WDT\_RST setting is for system reset 2. The dedicated watchdog timers are incorporated respectively in CA53 core 0 and core 1 and a system reset is applied when the counter of either watchdog timer overflows. **Table 45.6-11** lists the correspondence of connection between the CPG and WDT.  
For details, see **Section 45.8.11, Reset Range Selection Setting by a WDT Timeout**.

Table 45.6-11 Connection of the Watchdog Timer Reset

| Internal Pin of the CPG Unit |       |        | Supply Source Unit |          |
|------------------------------|-------|--------|--------------------|----------|
| Pin Name                     | I/O   | Active | Unit               | Pin Name |
| WDT_RST_N[0]                 | Input | Low    | WDT0               | WDTRSTB  |
| WDT_RST_N[1]                 | Input | Low    | WDT1               | WDTRSTB  |

### 45.6.2.2 List of Resets to be Applied

**Table 45.6-12** lists the resets to be applied for the respective units.

The numbers and symbols in the figure are as follows.

1. System reset
- 2a. CA53 SW warm reset (core 0)
- 2b. CA53 SW Warm Reset (core 1)
3. CA53 SW warm reset (core 1)

The meanings of the symbols in the figure are as follows.

- ✓: Resets to be asserted or de-asserted in response to the generation of any of the above reset sources
- : Resets not to be asserted or de-asserted in response to the generation of any of the above reset sources
- Reg: Depends on the software (the reset control register 1-15 (CPG\_RST1-15) setting).

Table 45.6-12 List of Resets to be Applied (1/3)

| UNIT   | Signal Name         | 1      |           | 2a     |           | 2b     |           | 3      |           |
|--------|---------------------|--------|-----------|--------|-----------|--------|-----------|--------|-----------|

### 45.6.2.3 Software Control Reset

Resetting can be controlled per unit by the CA53 accessing the reset control register of the CPG.

**Figure 45.6-21** shows the schematic diagram.

Figure 45.6-21 Schematic Diagram of Software Control Reset

#### 45.6.2.4 Unit Reset Control

The individual units can be reset or released from the reset state by the setting of the reset control register of the CPG (CPG\_RST1 to 15).

The method of resetting includes reset control TYPE-A and TYPE-B, and whether TYPE-A or TYPE-B is to be used depends the reset specification of the given units.

**Figure 45.6-22** is a schematic view of connections of the respective units and reset control TYPE-A and TYPE-B.

Figure 45.6-22 Schematic View of Connections of Reset Control TYPE-A and TYPE-B

(1) Reset Control TYPE-A

In the case of resetting by TYPE-A, stop the clock signal for the target unit by using the clock ON/OFF control register of the CPG (CPG\_CLK\_ON1 to 27) before de-asserting the reset signal in order to avoid contention between the timing of de-assertion of the reset and the clock signal.

After de-asserting the reset, supply the clock signal after an interval of at least one access cycle.

Switching the clock on or off is not required at the time of a reset.

The reset signal output to a given unit from the CPG can control resetting by the corresponding register bit of the CPG reset control register (CPG\_RST1 to 15).

When a system reset occurs, the reset signal is de-asserted after the clock has been stopped by hardware control. The control is returned to the CPG register following the de-assertion of the reset signal.

**Figure 45.6-23** and **Figure 45.6-24** show the timing charts and **Table 45.6-14** lists the correspondence between the resets and clocks for the respective units.

Figure 45.6-23 Timing of Asserting the TYPE-A Reset by the CPG Register

Figure 45.6-24 Timing of De-asserting the TYPE-A Reset by the CPG Register

Table 45.6-13 lists the related registers.

Table 45.6-13 List of the TYPE-A Reset Setting Registers

| Register Name                 | Abbreviation   | Function                  |
|-------------------------------|----------------|---------------------------|
| Clock ON/OFF control register | CPG_CLK_ON1-27 | Unit clock on/off setting |
| Reset control register        | CPG_RST1-15    | Unit reset setting        |

Figure 45.6-25 is a timing diagram when a system reset occurs.

Figure 45.6-25 TYPE-A Reset Timing by a System Reset

Table 45.6-14 Correspondence between the TYPE-A Reset Control Resets and Clocks (1/3)

| Unit     | Reset           |          |     | Corresponding Clock |          |      | Remarks |

**Note:** (1) Reset control register (CPG\_RST1-15) number  
 (2) Reset control register control bit  
 (3) Clock ON/OFF control register (CPG\_CLK\_ON1-27)  
 (4) Clock ON/OFF control register control bit

Note 1. For more information, contact a Renesas Electronics sales representative.

## (2) Reset Control TYPE-B

Units incorporated in this LSI includes the units which require clock supply during a reset (target units<sup>\*1</sup>). Therefore, even if the clock is switched off by the clock ON/OFF control register of the CPG at the time of a reset in response to the corresponding reset source, the clock is forcibly supplied over a certain period by hardware control.

For these units, control is required to stop the clock for several clock cycles, in order to avoid contention between the timing of a reset and release from the reset and the clock edge. Otherwise, switch the clock on or off by the CPG register.

In the case of resetting by TYPE-B, there is a delay over a certain period until the CPG output is released from the reset after reset release has been set. The reset state of the CPG output can be checked by reading the internal register of the CPG (CPG\_RST\_MON). Read the CPG\_RST\_MON register to check that the target unit is released from the reset state before operating this unit.

**Note 1.** Target units

DMAC, RAMA/B, GIC, ROM, SDIO/1, eMMC, SEC, ETHER, PWM, CSI, UART, WDT, SYC, VCD, DRP-AI, PMC, JPG

Figure 45.6-26 shows the timing chart.

Figure 45.6-26 TYPE-B Reset Timing by the CPG Register

Table 45.6-15 lists the related registers.

Table 45.6-15 List of the TYPE-B Reset Setting Registers

| Register Name                 | Abbreviation   | Function                  |
|-------------------------------|----------------|---------------------------|
| Clock ON/OFF control register | CPG_CLK_ON1-27 | Unit clock on/off setting |
| Reset control register        | CPG_RST1-15    | Unit reset setting        |
| Reset monitor register        | CPG_RST_MON    | Unit reset monitoring     |

Figure 45.6-27 is a timing diagram when a system reset occurs.

**Note:** (1) Reset control register (CPG\_RST1-15) number  
 (2) Reset control register control bit  
 (3) Clock ON/OFF control register (CPG\_CLK\_ON1-27)  
 (4) Clock ON/OFF control register control bit

Note 1. For more information, contact a Renesas Electronics sales representative.

#### 45.6.2.5 Software Reset Control for the CPG's Sub-Units Allocated in the Power Domain

Though most of the sub-units of the CPG are allocated in the PD\_AWO power domain, some sub-units of the CPG which control resetting of the clock signal are allocated in the power domain to which the units as the destinations for the clock and reset supply belong.

“CPG Reset” from the CPG reset generation block in **Figure 45.6-28** is only asserted when a system reset occurs, and it is not asserted when the power domain is switched from off to on by PMC control during normal operation.

Therefore, when switching the power domain from off to on during normal operation, the sub-units allocated in the power domain other than PD\_AWO must be initialized by a software reset with the CPG register.

Note that the power domains PD\_VIDEO0, PD\_VIDEO1A/B, PD\_RFX, PD\_DRPA, and PD\_CA53 are already used with the ISP support package, so do not reset them.

Figure 45.6-28 Block Diagram of the Allocation of the Power Domains of the CPG's Sub-Units

### ■ Initialization of the CPG's Sub-Units

The sub-units of the CPG which are allocated in the power domain other than PD\_AWO within the CPG are reset by setting the corresponding bit of the CPG power domain reset control register (CPG\_PD\_RST) to 0 and released from the reset state by setting the same bit to 1.

**Table 45.6-17** lists the reset settings for the sub-units of the CPG.

Table 45.6-17 List of the Reset Settings for the CPG's Sub-Units

| Field Name   | Reset Range                                                     |
|--------------|-----------------------------------------------------------------|
| PD_MEM_RSTB  | CPG's sub-unit PD_MEM allocated in the power domain PD_AWO      |
| PD_VD0_RSTB  | CPG's sub-unit PD_VD0 allocated in the power domain PD_VIDEO0   |
| PD_VD1A_RSTB | CPG's sub-unit PD_VD1A allocated in the power domain PD_VIDEO1A |
| PD_VD1B_RSTB | CPG's sub-unit PD_VD1A allocated in the power domain PD_VIDEO1B |
| PD_RFX_RSTB  | CPG's sub-unit PD_RFX allocated in the power domain PD_RFX      |

Note that the mode setting registers are included in the sub-units OTHER of the CPG.

The sub-units OTHER of the CPG are only initialized at the time of a system reset.

**Table 45.6-18** gives the reset range for the functions of the CPG's sub-units.

Table 45.6-18 Reset Effect Range for the Functions of the CPG's Sub-Units

| Field Name  | Reset Effect Range                |                                                                            |
|-------------|-----------------------------------|----------------------------------------------------------------------------|
| PD_MEM_RSTB | PLL/PLL control                   | PLL3, PLL3 control section                                                 |
|             | Divider (division ratio variable) | DIV_X*1                                                                    |
|             | Divider (division ratio fixed)    | DIV_X_DIV2                                                                 |
|             | Division ratio initialization     | DIV_X_REG_SYNC                                                             |
|             | Clock on/off                      | MMC_CORE_DDRC_CORE_CLK, MMC_ACLK,<br>MMC_PCLK, DDI_APBCLK,<br>ICB_MMC_ACLK |

Note 1. The CPG\_MMCDI\_DDIV register value is changed with the PLL3 clock within the CPG's sub unit PD\_MEM after it is retained with the Xtal clock and the changed value is initialized when PD\_MEM\_RSTB is set to 0.  
For the CPG\_MMCDI\_DDIV register, set the frequency division ratio after PD\_MEM\_RSTB is set to 1 and PLL3 is locked.

**Table 45.6-19** lists the related registers.

Table 45.6-19 List of the CPG's Sub-Unit Software Reset Control Register Allocated in the Power Domain

| Register Name                           | Abbreviation | Function                                              |
|-----------------------------------------|--------------|-------------------------------------------------------|
| CPG power domain reset control register | CPG_PD_RST   | Reset control per power domain of the CPG's sub-units |

## 45.7 Operating Procedure

### 45.7.1 Procedure for Writing to the Registers

The following registers consist of the 16 higher-order bits which are write enable and the 16 lower-order bits which are normal data registers, so changing only the value of the specified bits is possible without read-modify-write operations.

When changing the value, write 1 to the bit plus 16 of the bit to be changed.

*Example)*

To set bit[0] to 1b, write 0001\_0001h. To set it to 0b, write 0001\_0000h. The value of bit[15:0] is not changed when 0000\_xxxxh is written.

- Clock source setting (PLL/48MHz) register (CPG\_CLK48\_DSEL)
- Clock source setting (SDI/eMMC) register (CPG\_SDIEMM\_SSEL)
- Clock division ratio setting (GMCLK) register (CPG\_GMCLK\_SDIV)
- Clock source setting (GMCLK) register (CPG\_GMCLK\_SSEL)
- Clock source setting (CSI\_REF) register (CPG\_CSI\_RCLK\_SSEL)
- Clock ON/OFF control register n (CPG\_CLK\_ONn) n = 1 to 27
- WDT reset range select register (CPG\_WDT\_RST)
- Reset mask register (CPG\_RST\_MSK)
- Reset control register n (CPG\_RSTn) n = 1 to 15
- CPG power domain reset control register (CPG\_PD\_RST)

#### CAUTION

When read, the 16 higher-order bits are always read as 0.

The following registers are read-only, so writing has no effect.

- Clock status monitor register (CPG\_CLKSTATUS)
- Reset monitor register (CPG\_RST\_MON)

### 45.7.2 Procedure for Setting the Static Switching Divider and the Selector

Follow the procedure below when setting the frequency division ratio for the static switching divider and setting the clock for the selector. Basically, the procedure is as follows: Switching the corresponding clock off → Setting for switching → Switching the clock on.

\* The procedure for switching GMCLK0 (DIV T, SEL T) is described as an example.

#### 1. Setting for switching the general-purpose clock (GMCLK0) off

Set the following bit of the clock ON/OFF control register 7 (CPG\_CLK\_ON7).

- Setting for switching the clock off: Bit 4 (CLK4\_ON) = 0; bit 20 (CLK4\_ONWEN) = 1

#### 2. Setting the frequency division ratio for DIV T

Set the following bits of the clock division ratio setting (GMCLK) register (CPG\_GMCLK\_SDIV) while the clock supply is stopped after at least three cycles of the general-purpose clock have elapsed\*<sup>1</sup>.

- Setting the frequency division ratio: Bits 3 to 0 (DIVT\_SET) = any value\*<sup>2</sup>; bit 16 (DIVT\_WEN) = 1

#### 3. Setting the SEL T selector

Set the following bits of the clock source setting (GMCLK) register (CPG\_GMCLK\_SSEL).

- Setting the frequency division ratio: Bits 1 and 0 (SELT\_SET) = any value; bit 16 (SELT\_WEN) = 1

#### 4. Setting for switching the general-purpose clock (GMCLK0) on\*<sup>2</sup>

Set the following bits of the clock ON/OFF control register 7 (CPG\_CLK\_ON7)

- Setting for switching the clock on: Bit 4 (CLK4\_ON) = 1; bit 20 (CLK4\_ONWEN) = 1

**Note 1.** Reflection of the setting for switching the clock on or off in the clock pin depends on the clock.  
See "Clock ON/OFF Control Register 1 to 27 (CPG\_CLK\_ON 1 to CPG\_CLK\_ON27)", and **Section 45.8.6, Interval of Access to the Clock ON/OFF Control Registers.**

**Note 2.** The static switching divider requires up to one cycle of the clock before switching for reflection of the register value.

Accordingly, after setting the frequency division ratio, insert a wait of at least one cycle of the clock corresponding to the setting before switching.

The procedure above is applicable to the following registers.

- Clock source setting (SDI/eMMC) register (CPG\_SDIEMM\_SSEL)
- Clock division ratio setting (GMCLK) register (CPG\_GMCLK\_SDIV)
- Clock source setting (GMCLK) register (CPG\_GMCLK\_SSEL)
- Clock source setting (CSI\_REF) register (CPG\_CSI\_RCLK\_SSEL)

**CAUTION**

---

The setting for switching the clock on or off in steps 1 and 4 will be applied to the destination for propagation of the clock for which the setting is to be changed.

Check the clock source setting and change the setting after switching the target clock off.

If the clock source setting is changed without switching the clock off, the stable clock will not be output.

---

### 45.7.3 Setting Procedure for Switching the Clock On or Off

Follow the procedure below when making the setting for switching the clock on or off.

\* The procedure is described, taking the SDI0 clock (SDI0\_ACLK) as an example.

#### [Setting for Switching the Clock On]

1. Setting for switching the SDI0 clock (SDI0\_ACLK) on

Set the following bits of the clock ON/OFF control register 3 (CPG\_CLK\_ON3).

- Setting for switching the clock on: bit 0 (CLK0\_ON) = 1; bit 16 (CLK0\_ONWEN) = 1

The clock is output after three cycles of the SDI0 clock (SDI0\_ACLK) have elapsed\*<sup>1</sup> following the setting.

#### [Setting for Switching the Clock Off]

1. Setting for switching the SDI0 clock (SDI0\_ACLK) off

Set the following bits of the clock ON/OFF control register 3 (CPG\_CLK\_ON3).

- Setting for switching the clock off: bit 0 (CLK0\_ON) = 0; bit 16 (CLK0\_ONWEN) = 1

The clock is stopped after three cycles of the SDI0 clock (SDI0\_ACLK) have elapsed\*<sup>1</sup> following the setting.

**Note 1.** Reflection of the setting for switching the clock on or off in the clock pin depends on the clock.  
See "Clock ON/OFF Control Register 1 to 27 (CPG\_CLK\_ON 1 to CPG\_CLK\_ON27)".

The procedure above is applicable to the following registers.

- Clock ON/OFF control register n (CPG\_CLK\_ONn) n = 1 to 27

#### 45.7.4 Reset Setting Procedure (TYPE-A Reset)

Follow the procedure below when setting TYPE-A reset control.

The procedure is as follows: Reset → Switching the corresponding clock off → Release from the reset state → Switching the clock on.

\* The procedure is described, taking the IIC as an example.

##### 1. Asserting the IIC reset (IIC\_GPA\_PRESETN, IIC\_GRB\_PRESETN)

Set the following bits of the reset control register 6 (CPG\_RST6).

- Bit 8 (UNIT8\_RSTB) = 0b; bit 24 (UNIT24\_RST WEN) = 1b
- Bit 9 (UNIT9\_RSTB) = 0b; bit 25 (UNIT25\_RST WEN) = 1b

##### 2. Setting the IIC clock (IIC\_PCLK[1:0]) off

Set the following bits of the clock ON/OFF control register 9 (CPG\_CLK\_ON9).

- Bit 12 (CLK12\_ON) = 0b; bit 28 (CLK28\_ONWEN) = 1b

Set the following bits of the clock ON/OFF control register 10 (CPG\_CLK\_ON10).

- Bit 12 (CLK12\_ON) = 0b; bit 28 (CLK28\_ONWEN) = 1b

##### 3. De-asserting the IIC reset (IIC\_GPA\_PRESETN, IIC\_GRB\_PRESETN)

Set the following bits of the reset control register 6 (CPG\_RST6) while the clock supply is stopped after at least three cycles of the IIC clock have elapsed\*<sup>1</sup>.

- Bit 8 (UNIT8\_RSTB) = 1b; bit 24 (UNIT24\_RST WEN) = 1b
- Bit 9 (UNIT9\_RSTB) = 1b; bit 25 (UNIT25\_RST WEN) = 1b

##### 4. Setting the IIC clock (IIC\_PCLK[1:0]) on

Set the following bits of the clock ON/OFF control register 9 (CPG\_CLK\_ON9).

- Bit 12 (CLK12\_ON) = 1b; bit 28 (CLK28\_ONWEN) = 1b

Set the following bits of the clock ON/OFF control register 10 (CPG\_CLK\_ON10).

- Bit 12 (CLK12\_ON) = 1b; bit 28 (CLK28\_ONWEN) = 1b

##### 5. Waiting for stabilization

The unit is accessible following the elapse of a delay in the de-assertion for the target unit described in **Table 45.4-1, List of Reset Signals (1/3)** after up to three cycles of the IIC clock have elapsed\*<sup>1</sup>.

**Note 1.** The time until the setting for switching the clock on or off is reflected depends on the clock frequency to be used. When the “De-assertion Delay for Target Unit” column in the **Table 45.4-1, List of Reset Signals (1/3)** has an entry, start access to a given unit after a unit clock cycle delay (the latest clock) + a delay in the de-assertion for the target unit have elapsed.

The procedure above is applicable to the following registers.

- Reset control register n (CPG\_RSTn) n = 1 to 15
- Clock ON/OFF control register n (CPG\_CLK\_ONn) n = 1 to 27

This operating procedure applies to the reset pins indicated as TYPE-A under the “Reset Control Type” column in **Table 45.4-1, List of Reset Signals (1/3)**.

### 45.7.5 Reset Setting Procedure (TYPE-B Reset)

Follow the procedure below when setting TYPE-B reset control.

The procedure is as follows: Switching the corresponding clock on → Reset → Release from the reset state → Checking.

The procedure is described in the following two patterns, taking resetting of the DMAC as an example.

- 1) When not switching the clock off during a reset
- 2) When switching the clock off during a reset

Note that switching the clock on or off during a reset is as desired.

#### 1) When not switching the clock off during a reset

1. Setting for switching the DMAC clock (DMAA\_ACLK) on

Set the following bits of the clock ON/OFF control register 1 (CPG\_CLK\_ON1).

- Setting for switching the clock on: Bit 11 (CLK11\_ON) = 1; bit 27 (CLK11\_ONWEN) = 1

2. Asserting the DMAC reset

Set the following bits of the reset control register 1 (CPG\_RST1) while the clock is supplied after at least three cycles of the DMAC clock have elapsed\*1.

- Asserting the reset: Bit 7 (UNIT7\_RSTB) = 0; bit 23 (UNIT7\_RST WEN) = 1

3. De-asserting the DMAC reset

Set the following bits of the reset control register 1 (CPG\_RST1) after at least 729.17 ns + 5 \* DMAA\_ACLK (the minimum assertion period in **Table 45.4-1, List of Reset Signals (1/3)**) have elapsed following the reset setting.

- De-asserting the reset: Bit 7 (UNIT7\_RSTB) = 1; bit 23 (UNIT7\_RST WEN) = 1

4. Checking the completion of de-assertion of the DMAC reset

Check that bit 4 (DMAA\_RST\_MON) of the reset monitor register (CPG\_RST\_MON) = 0.

**Note 1.** Reflection of the setting for switching the clock on or off in the clock pin depends on the clock.  
See the description of "Clock ON/OFF Control Register 1 to 27 (CPG\_CLK\_ON 1 to CPG\_CLK\_ON27)".

## 2) When switching the clock off during a reset

### 1. Setting for switching the DMAC clock (DMAA\_ACLK) on

Set the following bits of the clock ON/OFF control register 1 (CPG\_CLK\_ON1).

- Setting for switching the clock on: Bit 11 (CLK11\_ON) = 1; bit 27 (CLK11\_ONWEN) = 1

### 2. Asserting the DMAC reset

Set the following bits of the reset control register 1 (CPG\_RST1) while the clock is supplied after at least three cycles of the DMAC clock have elapsed\*.<sup>1</sup>

- Asserting the reset: Bit 7 (UNIT7\_RSTB) = 0; bit 23 (UNIT7\_RST WEN) = 1

### 3. Setting for switching the DMAC clock (DMAA\_ACLK) off

Set the following bits of the clock ON/OFF control register 1 (CPG\_CLK\_ON1) after at least 729.17 ns + 5 \* DMAA\_ACLK (the minimum assertion period in **Table 45.4-1, List of Reset Signals (1/3)**) have elapsed following the reset setting.

- Setting for switching the clock off: Bit 11 (CLK11\_ON) = 0; bit 27 (CLK11\_ONWEN) = 1

The clock is stopped after three cycles of the DMAC clock have elapsed following the setting.

### 4. Setting for switching the DMAC clock (DMAA\_ACLK) on

Set the following bits of the clock ON/OFF control register 1 (CPG\_CLK\_ON1).

- Setting for switching the clock on: Bit 11 (CLK11\_ON) = 1; bit 27 (CLK11\_ONWEN) = 1

The clock is output after three cycles of the DMAC clock have elapsed following the setting.

### 5. De-asserting the DMAC reset

Set the following bits of the reset control register 1 (CPG\_RST1) after the resumption of the clock output.

- De-asserting the reset: Bit 7 (UNIT7\_RSTB) = 1; bit 23 (UNIT7\_RST WEN) = 1

### 6. Checking the completion of de-assertion of the DMAC reset

Check that bit 4 (DMAA\_RST\_MON) of the reset monitor register (CPG\_RST\_MON) = 0.

**Note 1.** Reflection of the setting for switching the clock on or off in the clock pin depends on the clock.  
See the description of “Clock ON/OFF Control Register 1 to 27 (CPG\_CLK\_ON 1 to CPG\_CLK\_ON27)”.

The procedure above is applicable to the following registers.

- Reset control register n (CPG\_RSTn) n = 1 to 15
- Clock ON/OFF control register n (CPG\_CLK\_ONn) n = 1 to 27
- Reset monitor register (CPG\_RST\_MON)

This operating procedure applies to the reset pins indicated as TYPE-B under the “Reset Control Type” column in **Table 45.4-1, List of Reset Signals (1/3)**.

## 45.8 Usage Notes

### 45.8.1 Note on Clock Control

Access to the units which have stopped the clock supply is prohibited.

### 45.8.2 Note on Reset Control

While the ICB is reset, access to the power domain to which that ICB belongs is prohibited.

When the ICB is released from the reset, it is disconnected if its power is off. The ICB must be accessed after checking that it has been released from the disconnection. For details, see the section of PMC.

### 45.8.3 Notes on External Pin Reset

The external pin reset RSTN, DESRSTN, and DETRSTN should be asserted for no less than 10  $\mu$ s. When a system reset is initiated by RSTN, DESRSTN, or DETRSTN, the external power switch of PD\_MEM is also turned off. Accordingly, secure the period for assertion of RSTN, DESRSTN, and DETRSTN such that the power supply voltage of PD\_MEM falls below 0.1 V within 10  $\mu$ s or to continue until the power supply voltage falls below 0.1 V. In addition, to switch the power supply for PD\_MEM on or off by using the external power switch, make sure that the power supply voltage is cut off within the above period or secure enough time for the assertion of RSTN, DESRSTN, and DETRSTN so that the power supply voltage has been cut off.

### 45.8.4 Restriction on the Dynamic Division Ratio Setting (Changing the Frequency)

Even when the setting has not been changed in the register setting for the dynamic divider, writing 1 to “xx\_WEN” allocated in the 16 higher-order bits of the register starts clock switching. Poll the status monitor register (CPG\_CLKSTATUS) to check the completion of switching (the clock is stopped once at the time of switching).

### 45.8.5 Restriction on the Dynamic Switching Selector (Clock Switching)

Even when the setting has not been changed in the register setting for the dynamic selector, writing 1 to “xx\_WEN” allocated in the 16 higher-order bits of the register starts clock switching. Poll the status monitor register (CPG\_CLKSTATUS) to check the completion of switching (the clock is stopped once at the time of switching).

### 45.8.6 Interval of Access to the Clock ON/OFF Control Registers

Clock on/off switching is reflected after synchronization with each clock following the register setting (synchronization with 48 MHz). Therefore, when clock on/off switching is to be set for the clock signals at the frequency lower than 48 MHz or those set to a frequency lower than 48 MHz, reflection of clock on/off switching takes time longer than cycles for register access.

**Table 45.8-1** lists the ON/OFF registers for the clock signals at the frequency lower than 48 MHz (those set to lower frequencies). For access to the same register bits with a lower frequency setting than 48 MHz, insert a wait by software to wait for at least the number of clock cycles listed in this table.

Table 45.8-1 List of ON/OFF Registers for the Clocks Less than 48 MHz

| Register                         |              |      | Clock Name      | Number of Clock Cycles                                       | Frequency (MHz)                                 | Wait Time (ns) <sup>*1</sup> |
|----------------------------------|--------------|------|-----------------|--------------------------------------------------------------|-------------------------------------------------|------------------------------|
| Name                             | Abbreviation | Bit  |                 |                                                              |                                                 |                              |
| Clock ON/OFF control register 1  | CPG_CLK_ON1  | 5    | GIC_CLK         | 3*GIC_CLK                                                    | 200/100/50/25/24                                | 125                          |

|                                  |              | 5    | VCD_PCLK        | 2*VCD_PCLK <sup>(1)</sup><br>+4*VCD_ACLK <sup>(2)</sup>      | ___*3                                           | 160                          |

Note 1. The maximum time until a change to the clock frequency is reflected (the number of clock cycles × the minimum frequency period).  
A change to the set frequency is completed after at least the time listed in the "Wait Time" column has elapsed, regardless of the changed value of the register setting.

Note 2. (1) and (2) are interlinked at the frequencies divided by a slash (/).

Note 3. For more information, contact a Renesas Electronics sales representative.

### 45.8.7 Restriction on the CSI Clocks

A restriction applies to the relation between the two CSI clocks (PCLK, CSI\_CLK) and the CSI\_CLK frequency must be set to no greater than half the PCLK frequency.

The variable bus clock SPCLK (100/50/48 MHz) is connected to PCLK of the CSI. CSI\_CLK connects the clock switched to 48 or 24 MHz. Therefore, when using SPCLK at 50 MHz or 48 MHz, be sure to set all CSI\_CLK from CSI0 to 5 to 24 MHz.

The related registers are listed below.

- System division ratio setting register (CPG\_SYS\_DDIV)  
DIV E (SPCLK 100/50 MHz switching) (bit 8)
- Clock source setting (PLL/48MHz) register (CPG\_CLK48\_DSEL)  
SEL E (SPCLK PLL/48 MHz switching) (bit 2)
- Clock source setting (CSI\_REF) register (CPG\_CSI\_RCLK\_SSEL)  
SEL CSI5-0 (CSI\_CLK 48/24 MHz switching) (bits 5 to 0)
- Clock ON/OFF control register 15 (CPG\_CLK\_ON15)  
CSI\_CLK ON/OFF setting (bits 13 to 8)

### 45.8.8 Register Control for CPG\_CLK\_ON16 and CPG\_CLK\_ON17

Access to the units subject to a reset is prohibited during the “Minimum Assertion Period” or the period of “De-assertion Delay for Target Unit” listed in **Table 45.4-1, List of Reset Signals (1/3)**.

### 45.8.9 Register Control of CPG\_CLK\_ON16 and CPG\_CLK\_ON17

Since stopping the ICB clock for the PD1\_AWO power domain causes the system to be deadlocked, the target bits of the CPG\_CLK\_ON16 and CPG\_CLK\_ON17 registers must always be left as 1b.

- Setting for switching the ICB\_CLK48 clock off
- Setting for asserting the ICB\_PD\_AWO\_RST\_N reset (setting CPG\_RST7.UNIT0\_RSTB to 0)

If the above settings have been made, restore the values by an external reset.

- CPG: CPG\_CLK\_ON16 register
 

|                                |                          |
|--------------------------------|--------------------------|
| Bit 0: ICB_ACLK1, ICB_GIC_CLK; | Bit 2: ICB_MPCLK1        |
| Bit 3: ICB_SPCLK1;             | Bit 4: ICB_CLK48         |
| Bit 10: ICB_CST_ATB_SB_CLK;    | Bit 11: ICB_CST_CS_CLK   |
| Bit 12: ICB_CLK100_1;          | Bit 13: ICB_ETH0_CLK_AXI |
| Bit 14: ICB_DCI_CLKAXI;        | Bit 15: ICB_SYC_CNT_CLK  |
- CPG: CPG\_CLK\_ON17 register
 

|                      |
|----------------------|
| Bit 0: ICB_DRPA_ACLK |
|----------------------|

#### 45.8.10 Restriction on Bit 5 (CLK5\_ON) of the CPG\_CLK\_ON19 Register

This register is a clock control register for access to the APB registers of the soft macro within CA53 (CA53\_SM). Since the clock supply is required when CA53 is operating, independently of the operating mode, debug mode or normal mode, bit 5 (CLK5\_ON) of the CPG\_CLK\_ON19 register must always be left as 1b.

#### 45.8.11 Reset Range Selection Setting by a WDT Timeout

Though the reset range by a WDT timeout can be set as system reset 2 or a CPU core warm reset by using the register (CPG\_WDT\_RST), a warm reset must be applied by following the procedure such as completion of the bus transaction. A reset by a WDT timeout is generated at an unexpected time, i.e., when software runs out of control.

Therefore, when a WDT timeout reset occurs without interlinked operation with software, a warm boot may not be done correctly, so the following settings are prohibited.

- WDT CA53 warm reset (core 0) setting (setting CPG\_WDT\_RST.WDTRST0 to 1)
- WDT CA53 warm reset (core 1) setting (setting CPG\_WDT\_RST.WDTRST1 to 1)

### 45.8.12 Restrictions on the CPG Reset Control Registers

**Table 45.8-2** lists the restrictions on reset control by software. Setting the corresponding bits of the reset control registers to 0b is prohibited (resetting by software is prohibited).

Table 45.8-2 Restrictions on the CPG Reset Control Registers

| Corresponding Bit of the Reset Control Register for which the Setting 0b is Prohibited | Register Function                           | Supplementary Note                                                                                           |
|----------------------------------------------------------------------------------------|---------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| CPG_RST1 register                                                                      |                                             |                                                                                                              |
| Bit 14 (UNIT14_RSTB)                                                                   | PMC_RESET_N (TYPE-B) reset pin control      | —                                                                                                            |
| Bit 1 (UNIT1_RSTB)                                                                     | SYS_RST_N (TYPE-A) reset pin control        |                                                                                                              |
| CPG_RST2 register                                                                      |                                             |                                                                                                              |
| Bit 10 (UNIT10_RSTB)                                                                   | CST_ATB_SB_RESETN reset pin control         | In debug mode, setting the corresponding bits of the reset control registers in the CPG to 0b is prohibited. |
| Bit 8 (UNIT8_RSTB)                                                                     | CST_APB_CA53_RESETN reset pin control       |                                                                                                              |
| Bit 7 (UNIT7_RSTB)                                                                     | CST_TS_SB_RESETN reset pin control          |                                                                                                              |
| Bit 6 (UNIT6_RSTB)                                                                     | CST_AHB_RESETN reset pin control            |                                                                                                              |
| Bit 5 (UNIT5_RSTB)                                                                     | CST_SB_RESETN reset pin control             |                                                                                                              |
| Bit 4 (UNIT4_RSTB)                                                                     | CST_TRESETN reset pin control               |                                                                                                              |
| Bit 3 (UNIT3_RSTB)                                                                     | CST_TS_RESETN reset pin control             |                                                                                                              |
| Bit 2 (UNIT2_RSTB)                                                                     | CST_CS_RESETN reset pin control             |                                                                                                              |
| Bit 1 (UNIT1_RSTB)                                                                     | CST_NPOTRST and CST_NTRST reset pin control |                                                                                                              |
| Bit 0 (UNIT0_RSTB)                                                                     | CST_NTRST reset pin control                 |                                                                                                              |
| CPG_RST7 register                                                                      |                                             |                                                                                                              |
| Bit 0 (UNIT0_RSTB)                                                                     | ICB_PD_AWO_RST_N reset pin control          | —                                                                                                            |

### 45.8.13 Restriction on the UART Clock Frequency

Since a 16x baud rate clock is used for 1-bit sampling, the UART serial clock (URT\_CLK[1:0]) must be set to at least 16 times the data transfer rate (baud rate) to be used (up to 108 MHz). For example, in a use case where the data transfer rate of the UART is 5 Mbps, set URT\_CLK[1:0] to at least 80 MHz (up to 108 MHz).

### 45.8.14 Restriction on the Frequencies of the General-Purpose Clocks (GMCLK0, GMCLK1)

The clock frequencies of GMCLK0 and GMCLK1 must be set to no greater than 100 MHz.

### 45.8.15 Point for Caution when Changing the Clock Setting

Operation when the clock setting is changed while the unit is operating cannot be guaranteed.

\* The CA53 clock (CA53\_CLK) is excluded.

## Section 46 Interconnect Bus (ICB)

This section describes the functions of the interconnect bus (ICB).

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 46.1 Functional Overview

**Table 46.1-1** is a list of the ICB functions.

Table 46.1-1 List of Functions

| Function                         | Overview                                                                                                                                                    |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access between master and slave  | <ul style="list-style-type: none"> <li>• Selecting an access path</li> <li>• Transaction conversion</li> </ul>                                              |
| Scheduler                        | <ul style="list-style-type: none"> <li>• Arbitration</li> </ul>                                                                                             |
| QoS                              | <ul style="list-style-type: none"> <li>• Priority control</li> </ul>                                                                                        |
| Bus separation                   | <ul style="list-style-type: none"> <li>• Detection and notification of the bus isolation status of the target power domain</li> </ul>                       |
| Observability                    |                                                                                                                                                             |
| Scheduler statistics measurement | <ul style="list-style-type: none"> <li>• Measures the amount of data transferred and the number of transactions that pass through the scheduler.</li> </ul> |

| TraceAlarm detection             | <ul style="list-style-type: none"> <li>• Detecting that a specific transaction has passed through the scheduler</li> </ul>                                  |
| ErrorLogging detection           | <ul style="list-style-type: none"> <li>• Detecting error responses to the master port</li> </ul>                                                            |
| ATB I/F output                   | <ul style="list-style-type: none"> <li>• The information on StatAlarm and TraceAlarm detection is output via ATB I/F.</li> </ul>                            |
| Interrupt                        | <ul style="list-style-type: none"> <li>• The interrupt notification of StatAlarm, TraceAlarm, and ErrorLogging detections</li> </ul>                        |

Table 46.1-2 List of Abbreviations

| Abbreviation | Description                                        |
|--------------|----------------------------------------------------|
| NIU          | Network interface unit                             |
| INIU         | Initiator NIU that interfaces with the master unit |
| TNIU         | Target NIU that interfaces with the slave unit     |
| NSP          | Network socket protocol                            |
| NoC          | Network on-chip                                    |
| NTTP         | Noc transaction and transport protocol             |

## 46.2 Internal Configuration

**Figure 46.2-1** shows the internal configuration of the ICB unit, which consists of the following elements

- ICB\_MAIN, the main body of NoC, and ICB\_REG for low-speed register access
- Initiator NIU (INIU) that interfaces with the master unit
- Target NIU (TNIU) that interfaces with the slave unit
- LPDDR4 scheduler
- Switch and Link of connection elements between INIU and TNIU
- Observability to observe error responses and statistical information
- The elements in this unit are located in the power domain<sup>\*1</sup> that is related to the ICB\_PD domain.

**Note 1.** Power domain: PD\_AWO, PD\_MEM, PD\_VIDEO0, PD\_VIDEO1, and PD\_RFX

Figure 46.2-1 Internal Configuration

## Section 47 External Power Sequence Controller (PWC)

This section describes the functions of the external power sequence controller (PWC).

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 47.1 Functional Overview

The PWC is a controller for external power supplies (regulators and power switches).

- Generating an external power supply on/off sequence
- Generating an on/off signal for the LPDDR4 core power supply (LPVDD)
- Generating control signals for external I/O power supplies of the SD host interfaces

### 47.2 Connection Configuration

Figure 47.2-1 is a connection configuration of the PWC.

Figure 47.2-1 Connection Configuration of the PWC

### 47.3 Pin Functions

**Table 47.3-1** lists the external pins of the PWC.

Table 47.3-1 List of External Pins

| Pin Name       | I/O    | Function                                                                                                                                  |
|----------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------|
| PWRSTN         | Input  | RTC reset input (active low)                                                                                                              |
| PWVBAT         | Input  | Battery voltage detection                                                                                                                 |
| PWEN5 to PWEN0 | Output | Power enable 5 to 0 (active high)                                                                                                         |
| PWSYSRSTN      | Output | System reset output.<br>Connected to the RSTN pin to use the power control function of PWC.                                               |
| PWSD0SEL       | Output | PWC SDI0 interface power supply selection                                                                                                 |
| PWSD1SEL       | Output | PWC SDI1 interface power supply selection                                                                                                 |
| PWMEMSWIENA    | Output | Enable signal output pin for controlling the LPVDD power supply on/off                                                                    |
| PWISO          | Output | RTC separation output pin. Open drain output.<br>Connected to the RTISO pin and pulled up (with 10kΩ to 100kΩ) to a 1.5-V power supply.*1 |

Note 1. The PWISO and RTISO pins are connected to this LSI, and these nodes should be pulled up with a 10-kΩ to 100-kΩ resistor. The schematic diagram is shown in **Section 2, Pin**. For details, refer to **Section 2**.

## 47.4 Register Description

For more information, contact a Renesas Electronics sales representative.

## 47.5 Functional Description

- External power supply on/off sequence generation

The PWC outputs enable signals (PWENn (n: 0 to 5)) to control the various external power supplies (regulators and power switches) required by this LSI chip and a system reset signal (PWSYSRSTN) for this chip.

**Figure 47.5-1** shows an example of a system configuration for external power supplies.

Figure 47.5-1 Example System Configuration for External Power Supplies

Note: This figure is an example and does not guarantee the operation of the external circuitry it shows. Follow the procedures described in **Section 51, Electrical Characteristics**.

- PWENn (n: 0 to 5) output pins:  
Being connected to the control pins of the external power supplies (regulators), these output pins control the rising and falling of the various power supply voltages.

Table 47.5-1 Functions of PWENn (n: 0 to 5) Pins

| Output Pin | Function                                                                                  |
|------------|-------------------------------------------------------------------------------------------|
| PWEN0      | Used to control the on/off state of the main external power supply (regulator).           |
| PWEN1      | Used to control the on/off status of the external power supply (regulator) for timing 1*1 |
| PWEN2      | Used to control the on/off status of the external power supply (regulator) for timing 2*1 |
| PWEN3      | Used to control the on/off status of the external power supply (regulator) for timing 3*1 |
| PWEN4      | Used to control the on/off status of the external power supply (regulator) for timing 4*1 |
| PWEN5      | Used to control the on/off status of the external power supply (regulator) for timing 5*1 |

Note 1. See the description in **Section 51, Electrical Characteristics**.

- PWSYSRSTN output pin:  
Connecting this output to the system reset control pin (the RSTN input pin) of this LSI chip allows reset control of the chip.

**Figure 47.5-2** shows the timing of the outputs from the PWENn (n: 0 to 5) and PWSYSRSTN pins.

Figure 47.5-2 Timing of the Outputs from the PWENn (n: 0 to 5) and PWSYSRSTN Pins

Control of the external power supplies by an external PMIC (power management IC) or similar without using the PWENn (n: 0 to 5) outputs of the PWC is also possible. For details on the specifications for the relative timing of rising and falling voltages on the power supply pins of this LSI chip, see the description in **Section 51, Electrical Characteristics**.

- Generating an on/off signal for the LPDDR4 core power supply (LPVDD)
  - PWMEMSWIENA output pin: Enable signal output pin for controlling the LPVDD power supply on/off

LPVDD is the power supply for the on-chip LPDDR memory controller unit (power supply domain PD\_MEM (0.8-V power supply system)), and turning on/off the LPVDD power supply is individually controlled by the System FW of this LSI after booting.

Supply 0.8-V power to LPVDD through the power switch. Connect the PWMEMSWIENA pin to the enable pin of this power switch.

- Generating control signals for external I/O power supplies of the SD host interfaces

Control signals PWSDnSEL (n: 0, 1) are output for switching of the IO power supply voltages (between 1.8 V and 3.3 V).

With a multi-output regulator for these IO power supplies, the IO voltages can be switched from 3.3 V to 1.8 V or from 1.8 V to 3.3 V by using signals on the PWSDnSEL (n: 0, 1) pins.

- PWSD0SEL output pin: For switching the IO power supply voltage of SD host interface SDI0
- PWSD1SEL output pin: For switching the IO power supply voltage of SD host interface SDI1

In the external power supply configuration example shown in **Figure 47.5-1**, this LSI executes the power-up sequence when the PWC detects a startup source after the PWC reset (PWRSTN) is released.

- Startup source

The power supply for starting up this LSI is detected (a change from low to high on the PWVBAT pin is detected).

- Supplementary note

- 1) When PWVBAT is driven high after 750 ms to 1250 ms have elapsed since PWRSTN was driven high  
PWEN0 is driven high after 7.8 to 23.4 ms have elapsed since PWVBAT was driven high.
- 2) When PWVBAT is driven high before 750 ms to 1250 ms have elapsed since PWRSTN was driven high  
PWEN0 is driven high after 757.8 to 1257.8 ms have elapsed since PWRSTN was driven high.

*Note:* When PWVBAT is not used and pulled up by PWVDD, the operation is as described in 2).

## Section 48 Internal Power Domain Controller (PMC)

This section describes the functions of the internal power domain controller (PMC).

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 48.1 Functional Overview

#### 48.1.1 List of Functions

**Table 48.1-1** is a list of the functions of the PMC.

Table 48.1-1 List of Functions

| Function<br>(Major Category)                          | Functions                            | Description                                                                                                                                                                                                                                                           |
|-------------------------------------------------------|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Internal power domain<br>on/fff control* <sup>1</sup> | Internal power domain on/fff control | Controls the on/off state of the internal power domain. <ul style="list-style-type: none"> <li>Controls the SoC external power switch for PD_MEM</li> <li>Controls the SoC internal power switches for PD_VIDEO0, PD_VIDEO1, PD_RFX, PD_DRPA, and PD_CA53.</li> </ul> |
|                                                       | Isolation cell control* <sup>2</sup> | This function fixes the level of the signal output from the power-off domain.                                                                                                                                                                                         |
|                                                       | Bus idle request control             | Controls the separation/connection of the buses of the units in PD_MEM, PD_VIDEO0, PD_VIDEO1, and PD_RFX from ICB.                                                                                                                                                    |
| Interrupt control                                     | Interrupt output control             | <ul style="list-style-type: none"> <li>Interrupt signal output (Internal power domain on/off control completed, bus separation completed)</li> <li>Clearing of interrupt sources</li> <li>Mask control of interrupt pins</li> </ul>                                   |
| CPU standby control                                   | CPU standby detection                | Allows the CPU to execute a WFI instruction to detect its transition to the standby state and indicate this in response to an interrupt (SPI).                                                                                                                        |
|                                                       | CPU RAM standby control              | Controls the standby state of the SRAM (cache) after a transition of the CPU of CA53 to the standby state (retention/shutdown).                                                                                                                                       |

Note 1. The software controls a series of processes from controlling the internal power domain on/off to controlling the isolation cells.

Note 2. The isolation cell prevents undefined propagation and through-current from power-off units to power-on units.

48.1.2 Internal Power Domain

The internal power domain of this LSI is divided into seven different power domain areas, including the always-on domain (PD\_AWO: Power Domain Always On). **Figure 48.1-1** shows te power domain of this LSI. This diagram is a schematic for explanation purposes only. The main function of the PMC is to power on and off these domains. Among these domains, PD\_CA53, PD\_VIDEO0, PD\_VIDEO1, PD\_RFX, and PD\_DRPA are used in the ISP support package. Therefore, rewriting the related registers is prohibited.

Figure 48.1-1 Power Domains to be Controlled

There are six power domains that the PMC can power on/off: PD\_MEM, PD\_VIDEO0, PD\_VIDEO1, PD\_RFX, PD\_DRPA, and PD\_CA53, except for PD\_AWO. PD\_VIDEO1 is physically distributed in two areas (PD\_VIDEO1\_0 and PD\_VIDEO1\_1). PD\_VIDEO1\_0 and PD\_VIDEO1\_1 cannot be individually controlled for power domain on/off. In addition to the above, there are two other power domains, RTC 0.8V and PWC 0.8V. PD\_AWO's power domain on/off is controlled by PWC, not by PMC.

**Table 48.1-2** shows the on/off status of the respective power domains after the system reset is released.

Table 48.1-2 Power Domain and Initial State

|               | PD_AWO   | PD_MEM    | PD_VIDEO0 | PD_VIDEO1 | PD_RFX    | PD_DRPA   | PD_CA53  |
|---------------|----------|-----------|-----------|-----------|-----------|-----------|----------|
| Initial state | Power on | Power off | Power off | Power off | Power off | Power off | Power on |

**Note:** The table shows the initial value settings of the PMC control registers.

## 48.2 Register Description

For details on the base address of the register (<PMC\_S0\_base>), see the Address Map section.

### 48.2.1 List of Registers

**Table 48.2-1** is a list of registers. The registers should be accessed in 32-bit units.

Table 48.2-1 List of Registers

| Offset Address | Register Name                             | Abbreviation        | Initial Value | Access Unit (bits) |
|----------------|-------------------------------------------|---------------------|---------------|--------------------|
| 000h           | Power Supply Enable Register              | PMC_SPLY_ENA        | 0000_0000h    | 32                 |

## 48.2.2 Register Descriptions

The function description of each register is given below.

### 48.2.2.1 Power Supply Enable Register (PMC\_SPLY\_ENA)

PMC\_SPLY\_ENA controls the power on/off process for the specified power domain. Write the ON bit and PD\_NUM bits at the same time.

Set this register after confirming that PD\_BUSY of the PMC\_MAIN\_STS register is 0. When this register is read, the last written value can be read.

**Note:** After starting the power on/off process, an interrupt occurs when the power switch is turned on/off. Isolation processing is not performed.

**Access Size:** 32 bits

**Address(es):** <PMC\_S0\_base> + 0000h

**Initial Value:** 0000\_0000h

Note 1. The value is confirmed when PD\_BUSY = 0. The value is indeterminate while PD\_BUSY = 1.

### 48.2.2.3 PD\_MEM Power-on/off Time Setting Register (PMC\_PD\_MEM\_TIM)

PMC\_PD\_MEM\_TIM sets the time required for the external power switch response of power domain PD\_MEM.

The maximum time that can be set to the PD\_ON\_TIM and PD\_OFF\_TIM bits is 21.8453 msec.

**Access Size:** 32 bits

**Address(es):** <PMC\_S0\_base> + 0014h

**Initial Value:** 0BB7\_0BB7h

#### 48.2.2.4 PD\_MEM Isolation Enable Register (PMC\_PD\_MEM\_ISOEN)

The isolation cell prevents the undefined value from propagating when the power domain PD\_MEM is turned off.

PMC\_PD\_MEM\_ISOEN sets the level of the isolation enable signal. After writing to the PD\_ISOEN bit, the time to stabilize the internal state is required. When the PD\_ISO\_DONE bit is '1b', the internal state is stable.

**Access Size:** 32 bits

**Address(es):** <PMC\_S0\_base> + 001Ch

**Initial Value:** 0000\_8001h

#### 48.2.2.5 PD\_VIDEO0 Isolation Enable Register (PMC\_PD\_VIDEO0\_ISOEN)

The isolation cell prevents the undefined value from propagating when the power domain PD\_VIDEO0 is turned off.

PMC\_PD\_VIDEO0\_ISOEN sets the level of the isolation enable signal. After writing to the PD\_ISOEN bit, the time to stabilize the internal state is required. When the PD\_ISO\_DONE bit is '1b', the internal state is stable.

**Access Size:** 32 bits

**Address(es):** <PMC\_S0\_base> + 0020h

**Initial Value:** 0000\_8001h

#### 48.2.2.7 PD\_RFX Isolation Enable Register (PMC\_PD\_RFX\_ISOEN)

The isolation cell prevents the undefined value from propagating when the power domain PD\_RFX is turned off.

PMC\_PD\_RFX\_ISOEN sets the level of the isolation enable signal. After writing to the PD\_ISOEN bit, the time to stabilize the internal state is required. When the PD\_ISO\_DONE bit is '1b', the internal state is stable.

**Access Size:** 32 bits

**Address(es):** <PMC\_S0\_base> + 0028h

**Initial Value:** 0000\_8001h

| Bit Position | Bit Name    | Description                                                                                                                                                                     |
|--------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 16     | —           | Reserved. These bits are read as 0b.                                                                                                                                            |
| 15           | PD_ISO_DONE | This bit indicates the isolation status inside the SoC.<br>0b: The internal state of the SoC is unstable during the isolation process.<br>1b: SoC internal isolation is stable. |
| 14 to 1      | —           | Reserved. These bits are read as 0b.                                                                                                                                            |
| 0            | PD_ISO_EN   | This bit sets the power domain PD_DRPA isolation.<br>0b: Release the fixed output signal (isolation).<br>1b: Fix the output signal (isolation).                                 |

#### 48.2.2.9 PD\_CA53 Isolation Enable Register (PMC\_PD\_CA53\_ISOEN)

The isolation cell prevents the undefined value from propagating when the power domain PD\_CA53 is turned off.

PMC\_PD\_CA53\_ISOEN sets the level of the isolation enable signal. After writing to the PD\_ISOEN bit, the time to stabilize the internal state is required. When the PD\_ISO\_DONE bit is '1b', the internal state is stable.

**Note:** The initial value of PD\_ISO\_EN is 0b, but the isolation is enabled immediately after the system reset is released. Isolation is released immediately before CA53 boots.

**Access Size:** 32 bits

**Address(es):** <PMC\_S0\_base> + 0034h

**Initial Value:** 0000\_8000h

|               |             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |

### 48.2.2.10 Idle Request Register (PMC\_IDLE\_REQ)

PMC\_IDLE\_REQ controls a request to separate the bus master port and bus slave port of the unit in the power domain PD\_#NAME (PD\_MEM, VIDEO0, VIDEO1, RFX).

**Access Size:** 32 bits

**Address(es):** <PMC\_S0\_base> + 0038h

**Initial Value:** 0000\_001Eh

### 48.2.2.11 Idle Request Status Register (PMC\_IDLE\_STS)

PMC\_IDLE\_STS indicates the status of bus separation and connection.

Physical power domains PD\_VIDEO1\_0 and PD\_VIDEO1\_1 return the status of the logical power domain PD\_VIDEO1.

**Access Size:** 32 bits

**Address(es):** <PMC\_S0\_base> + 003Ch

**Initial Value:** 0000\_001Eh

| Bit           | 31 | 30 | 29 | 28              | 27                 | 26                 | 25              | 24 | 23 | 22 | 21 | 20               | 19                  | 18                  | 17               | 16 |

| Bit Position | Bit Name  | Description                                                                                                                                                                                                                     |
|--------------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 6      | —         | Reserved. These bits are read as 0b.                                                                                                                                                                                            |
| 5            | L2_STBY   | Reads whether there is a standby (L2 Wait for Interrupt) detection interrupt for CA53.<br>0b: No interrupt factor has occurred. Or the interrupt factor has been released.<br>1b: An interrupt factor has occurred.             |
| 4            | CPU1_STBY | Reads whether there is a standby (Core Wait for Interrupt) detection interrupt for core 1 of CA53.<br>0b: No interrupt factor has occurred. Or the interrupt factor has been released.<br>1b: An interrupt factor has occurred. |
| 3            | CPU0_STBY | Reads whether there is a standby (Core Wait for Interrupt) detection interrupt for core 0 of CA53.<br>0b: No interrupt factor has occurred. Or the interrupt factor has been released.<br>1b: An interrupt factor has occurred. |
| 2            | —         | Reserved. When read, the value read is undefined.                                                                                                                                                                               |
| 1            | IDLE_DONE | Reads whether there is a bus separation completion interrupt for any power domain.<br>0b: No interrupt factor has occurred. Or the interrupt factor has been released.<br>1b: An interrupt factor has occurred.                 |
| 0            | PD_DONE   | Reads whether there is a power domain power on/off process completion interrupt.<br>0b: No interrupt factor has occurred. Or the interrupt factor has been released.<br>1b: An interrupt factor has occurred.                   |

#### 48.2.2.14 Interrupt Clear Register (PMC\_INT\_CLR)

PMC\_INT\_CLR clears the interrupt source of Interrupt Status Register (PMC\_INT\_STS).

Writing '1b' to the bit field of this register clears the corresponding bit in the interrupt status register PMC\_INT\_STS. Writing a '0b' does not change the corresponding bit in the interrupt status register PMC\_INT\_STS. If an interrupt request is detected simultaneously with the clearing of the interrupt source, the interrupt request has priority and the specified bit is set to 1b.

**Access Size:** 32 bits

**Address(es):** <PMC\_S0\_base> + 0048h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21       | 20        | 19        | 18   | 17        | 16      |

### 48.3 Functional Description

### 48.3.1 Connection Overview

**Figure 48.3-1** shows an overview of the peripheral connections for power control of the PMC.

Figure 48.3-1 Overview of Control Signal Connection

48.3.2 Internal Power Domain On/Off Control

Figure 48.3-2 shows a block diagram of the internal power domain on/off control function.

Figure 48.3-2 Internal Power Domain On/Off Control

### 48.3.2.1 Internal Power Domain On/Off Control

The power domain on/off control is performed by PMC\_SPLY\_ENA. The power domain to be controlled is set by the PD\_NUM bit.

It is possible to confirm that the power domain on/off process is in progress with PMC\_MAIN\_STS. When the power domain on/off process is completed, the PD\_#NAME\_ON bit is set to 1 (power on) or 0 (power off).

#### CAUTION

As shown in **Figure 48.3-2**, power domains other than PD\_MEM have internal power switches and can be controlled on/off by registers. In the other hand, PD\_MEM controls the on/off state of the power domain by controlling an external power switch. The external power switch can be controlled by the enable signal output from the PWMEMSWIENA pin via the PWC. When PWC and RTC are in the reset state, PWMEMSWIENA is fixed to low.

### 48.3.2.2 Internal Power Domain On/Off Completion Interrupt

The completion of the power domain on/off process can be notified as an interrupt. The interrupt factor can be checked by reading PMC\_INT\_STS. The default state after a reset is masked. Therefore, cancel the mask setting of PMC\_INT\_MSK if an interrupt is to be notified.

After the interrupt signal is detected by the CPU, clear the interrupt notification with PD\_DONE in PMC\_INT\_CLR.

### 48.3.2.3 Internal Power Domain On/Off Time Setting

Since PD\_MEM uses an external power switch, the power domain on/off time must be set in advance according to the startup time of the external power supply. The setting is made by PMC\_PD\_MEM\_TIM. After the set time has elapsed, an interrupt is notified by PMC\_INT\_STS.

### 48.3.2.4 Related Registers

Table 48.3-1 Power On/Off Control Related Registers

| Register Abbreviation | Bit Name    | Function                                                             |
|-----------------------|-------------|----------------------------------------------------------------------|
| PMC_SPLY_ENA          | ON          | Controls power on/off.                                               |
|                       | PD_NUM      | Specifies the target domain for power on/off.                        |
| PMC_MAIN_STS          | PD_BUSY     | Indicates the status of the power-on or power-off sequence process.  |
|                       | PD_#NAME_ON | Reads the power status (on/off) of the respective power domain.      |
| PMC_PD_MEM_TIM        | PD_OFF_TIM  | Sets the margin time until the external power switch is turned off.  |
|                       | PD_ON_TIM   | Sets the margin time until the external power switch is turned on.   |
| PMC_INT_STS           | IDLE_DONE   | Reads the bus separation completion interrupt status.                |
|                       | PD_DONE     | Notifies the completion of power on/off control.                     |
| PMC_INT_CLR           | IDLE_DONE   | Clears the bus separation completion interrupt.                      |
|                       | PD_DONE     | Clears the power-on/off control completion interrupt.                |
| PMC_INT_MSK           | IDLE_DONE   | Masks the notification of bus separation completion interrupt.       |
|                       | PD_DONE     | Masks the notification of power on/off control completion interrupt. |

**Note:** #NAME = MEM, VIDEO0, VIDEO1, RFX, DRPA, CA53

48.3.3 Isolation Cell Control

Figure 48.3-3 shows a block diagram of the isolation cell control function.

Figure 48.3-3 Isolation Cell Control

### 48.3.3.1 Isolation Settings

When the power switch is turned off, the undefined propagation output from the power domain must be suppressed (isolated). The isolation is set by PMC\_PD\_#NAME\_ISOEN. The PD\_ISO\_DONE bit indicates that the isolation has stabilized.

### 48.3.3.2 Isolation Release

The isolation is released by PMC\_PD\_#NAME\_ISOEN. After releasing the isolation, 104 nsec (5clk@PCLK) is required for the internal signal level to be stabilized.

Make sure that the PD\_ISO\_DONE bit in PMC\_PD\_#NAME\_ISOEN is set to 1 before starting the unit operation for the respective power domain.

### 48.3.3.3 Related Registers

Table 48.3-2 Isolation Control Related Registers

| Register Abbreviation | Bit Name    | Function                              |
|-----------------------|-------------|---------------------------------------|
| PMC_PD_#NAME_ISOEN    | PD_ISO_DONE | Checks the isolation stability state. |
|                       | PD_ISO_EN   | Enables the isolation.                |

**Note:** #NAME = MEM, VIDEO0, VIDEO1, RFX, DRPA, CA53

### 48.3.4 Bus Idle Request Control

The interconnected bus (ICB) has a function to logically separate the bus I/F from the units in the power supply domains PD\_MEM, PD\_VIDEO0, PD\_VIDEO1, and PD\_RFX. When the ICB receives a bus isolation request from this unit, it notifies the completion of all bus transactions (bus idle) in the relevant power domain.

In the case of an accidental access to a bus-separated unit, the ICB returns an error response instead of the slave. This prevents the bus from deadlocking.

#### CAUTION

Although only the AXI slave port of MMC has the bus isolation function of the power domain PD\_MEM, the APB register slave port of MMC and the APB register slave port of DDI do not have the bus isolation function.

Therefore, do not access the APB register slave port of the MMC and the APB register slave port of the DDI in the bus isolated state.

#### 48.3.4.1 Bus Separation

The bus separation is requested to the ICB by PMC\_IDLE\_REQ. The completion of all bus transactions (completion of bus separation) in the corresponding power domain can be checked by reading PMC\_IDLE\_STS.

The completion of the bus separation can also be notified as an interrupt. The interrupt factor can be checked by reading PMC\_INT\_STS. The default state after a reset is masked. Therefore, cancel the mask setting of PMC\_INT\_MSK if an interrupt is to be notified.

#### 48.3.4.2 Bus Connection

The bus separation request withdrawal (bus connection request) sets the PD\_#NAME\_IDLE\_REQ bit in PMC\_IDLE\_REQ to 0. The bus connection status can be checked with PMC\_IDLE\_STS.

#### CAUTION

The function to notify the completion of bus connection as an interrupt is not provided. However, if a bus separation request is withdrawn (PD\_#NAME\_IDLE\_REQ is set to 0) and a bus separation state is entered at the same time, a bus separation process completion interrupt may be generated.

### 48.3.4.3 Related Registers

Table 48.3-3 Bus Idle Request Control Related Registers

| Register Abbreviation | Bit Name           | Function                                                                                            |
|-----------------------|--------------------|-----------------------------------------------------------------------------------------------------|
| PMC_IDLE_REQ          | PD_#NAME_IDLE_REQ  | Requests bus isolation for units in the power domain.                                               |
| PMC_IDLE_STS          | PD_#NAME_ACT_DONE  | The status of the bus connection can be checked during bus processing for a bus separation request. |
|                       | PD_#NAME_IDLE_DONE | The status of bus separation can be checked during bus processing for a bus separation request.     |
| PMC_INT_STS           | IDLE_DONE          | Reads the bus separation completion interrupt status.                                               |
|                       | PD_DONE            | Notifies the completion of power on/off control.                                                    |
| PMC_INT_CLR           | IDLE_DONE          | Clears the bus separation completion interrupt.                                                     |
|                       | PD_DONE            | Clears the power-on/off control completion interrupt.                                               |
| PMC_INT_MSK           | IDLE_DONE          | Masks the notification of bus isolation completion interrupt.                                       |
|                       | PD_DONE            | Masks the notification of power on/off control completion interrupt.                                |

**Note:** #NAME = MEM, VIDEO0, VIDEO1, RFX

#### CAUTION

**Table 48.3-4** lists the enable/disable state of bus access and power-off for various states of the PD\_#NAME\_IDLE\_REQ bit in PMC\_IDLE\_REQ and the PD\_#NAME\_IDLE\_DONE and PD\_#NAME\_ACT\_DONE bits in PMC\_IDLE\_STS.

Table 48.3-4 Bus Idle Request Status

|                            | PD_#NAME_IDLE_REQ | PD_#NAME_ACT_DONE | PD_#NAME_IDLE_DONE | Bus Access | Power-off |
|----------------------------|-------------------|-------------------|--------------------|------------|-----------|
| Bus connection             | 0                 | 1                 | 0                  | Enabled    | Disabled  |
| Bus separation in progress | 1                 | 0                 | 0                  | Disabled   | Disabled  |
| Bus separation             | 1                 | 0                 | 1                  | Disabled   | Enabled   |
| Bus connection in progress | 0                 | 0                 | 0                  | Disabled   | Disabled  |
| Bus (re)connection         | 0                 | 1                 | 0                  | Enabled    | Disabled  |

**Note:** #NAME = MEM, VIDEO0, VIDEO1, RFX

### 48.3.5 CPU Standby Detection

#### 48.3.5.1 Functional Description

The CPU standby detection function detects that core 0 or core 1 of CA53 has entered the standby state by executing a WFI instruction and outputs an interrupt request INT\_PMC.

The standby state of the CPU is detected by the CA53\_STANDBYWFI[1:0] and CA53\_STANDBYWFIL2 signals of CA53. The interrupt status can be checked by the L2\_STBY, CPU1\_STBY, and CPU0\_STBY bits of PMC\_INT\_STS. Also, the CA53\_STANDBYWFI[1:0] and CA53\_STANDBYWFIL2 signals of CA53 can be monitored by using the PMC\_CPU\_MON register.

#### 48.3.5.2 Related Registers

Table 48.3-5 CPU Standby Detection Related Registers

| Register Abbreviation | Bit Name  | Function                                        |
|-----------------------|-----------|-------------------------------------------------|
| PMC_INT_STS           | L2_STBY   | Indicates the interrupt status of the L2 cache. |
|                       | CPU1_STBY | Indicates the interrupt status of CPU core 1.   |
|                       | CPU0_STBY | Indicates the interrupt status of CPU core 0.   |
| PMC_CPU_MON           | L2_STBY   | Indicates the standby state of the L2 cache.    |
|                       | CPU1_STBY | Indicates the standby state of CPU core 1.      |
|                       | CPU0_STBY | Indicates the standby state of CPU core 0.      |

## 48.3.6 CPU Standby Control

### 48.3.6.1 Functional Description

CPU standby control is for controlling standby of the CPU SRAM. This LSI can only handle standby control for core 1. Standby control for core 0 and the L2 cache is prohibited.

### 48.3.6.2 Related Registers

Two registers are used to set software standby control for the SRAM (L2 cache, core 0 L1 cache, core 1 L1 cache) of CA53.

[Setting the mode for standby of the SRAM]

- PMC\_CA53\_SDM\_CFG register:

- L2 bit
  - 0: Reserved
  - 1: Shutdown
- C1L1 bit
  - 0: Reserved
  - 1: Shutdown
- C0L1 bit
  - 0: Reserved
  - 1: Shutdown

[Setting standby of the SRAM]

- PMC\_CA53\_RS\_CTL register:

- L2 bit
  - 0: Normal
  - 1: Standby
- C1L1 bit
  - 0: Normal
  - 1: Standby
- C0L1 bit
  - 0: Normal
  - 1: Standby

### 48.3.6.3 CA53 standby level

The standby state of CA53 has the following levels. When making the settings, core 0 of CA53 is set as a master CPU and core 1 as a slave CPU.

Table 48.3-6 CA53 Standby Level

| Operating Mode |             | Master Core |           | Slave Core               |                    | L2 Cache  | Core mode   |
|----------------|-------------|-------------|-----------|--------------------------|--------------------|-----------|-------------|
|                |             | Logic       | L1 Cache  | Logic                    | L1 Cache           |           |             |
| Run            | Normal      | Normal      | Normal    | Normal                   | Normal             | Dual core | —           |
| Standby mode   | Standby LV1 | Normal      | Normal    | Individual core shutdown | Normal             | Normal    | Single core |
|                | Standby LV2 | Normal      | Normal    | Individual core shutdown | standby (shutdown) | Normal    | Single core |
| Power Off      |             | Power Off   | Power Off | Power Off                | Power Off          | Power Off | —           |

**Note:**

- Normal: The normal operating state in which the clock is operating.
- Individual core shutdown: For individual core shutdown mode, refer to steps 1 to 7 of the power down sequence in the “Individual core shutdown mode” section in “2.4.2 Power modes” of *the ARM Cortex-A53 MPCore Processor Technical Reference Manual*. Since this LSI does not have a power-off function for individual cores, it only covers the state up to the point where Wait for interrupt is executed in response to a cache flush.
- Standby (shutdown): A state in which the SRAM has entered shutdown mode.
- Power Off: A state in which power is not supplied to the power domain (PD\_CA53).

## 48.3.6.4 CA53 Standby State Transition Diagram

Figure 48.3-4 CA53 Standby Level State Transition Diagram

## 48.4 Operating Procedure

For more information, contact a Renesas Electronics sales representative.

## 48.5 Constraints

The PMC has the following constraints.

Table 48.5-1 Functional Constraints

| Classification       | Item                                      | Constraints                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Power domain control | Multiple power domain control             | While the power-on/off process is in progress, writing a power-on or power-off command to the PMC_SPLY_ENA register will be ignored. The process being executed will continue without stopping. The ignored command will not be started after the completion of the process being executed.                                                                                                 |
|                      | Power domain control                      | When an instruction to start power-on control is given to the power domain in the power-on state, the power-on process is performed and an interrupt is output. In a similar way, when an instruction to start power-off control is given to a power domain in the power-off state, the power-off process is performed and an interrupt is output. The power on/off status will not change. |
|                      | Power on/off time for power domain PD_MEM | The PMC_PD_MEM_TIM register, that holds the time required to power on/off the power domain PD_MEM, can be set to a value of up to 21.8 msec. Do not use an external power switch that takes more than 21.8 msec to turn on/off.                                                                                                                                                             |
|                      | Power domain access                       | The bus access to the power off power domain is prohibited.                                                                                                                                                                                                                                                                                                                                 |

## Section 49 System Configuration (SYS)

This section describes the functions of the system configuration (SYS).

### 49.1 Functional Overview

The SYS controls the overall configuration of the chip.

Table 49.1-1 Functions of SYS in Outline

| Category                  | Function             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| System configuration unit | System configuration | <ul style="list-style-type: none"><li>• Bank address settings for DMAC</li><li>• Bank address settings of the units for ICB</li><li>• ETHER AxCACHE[1] (C bit) control function</li><li>• RAMA initialization control</li><li>• MD[7:0] pin monitoring</li><li>• LSI version register</li><li>• General-purpose 32-bit readable/writable registers</li><li>• Observability counting stop control for ICB</li><li>• WDT counter stop control</li><li>• Reading of the temperature sensor reference value</li></ul> |

## 49.2 Pin Functions

### 49.2.1 List of Internal Pins

#### 49.2.1.1 List of DMAC DMAC0 Bank Address Pins

**Table 49.2-1** lists the internal pins (bank address pins for DMAC DMAC0).

Table 49.2-1 List of Internal Pins

| Pin Name                           | I/O    | Function                                                      |
|------------------------------------|--------|---------------------------------------------------------------|
| DMAC DMAC0 Bank Address Signals    |        |                                                               |
| DMAA_DMAL0_CH0_SRC_BANK_ADDR[1:0]  | Output | DMAC_DMAL0 Ch0 bank address control pin (for the source)      |
| DMAA_DMAL0_CH0_DST_BANK_ADDR[1:0]  | Output | DMAC_DMAL0 Ch0 bank address control pin (for the destination) |
| DMAA_DMAL0_CH0_DESC_BANK_ADDR[1:0] | Output | DMAC_DMAL0 Ch0 bank address control pin (for the descriptor)  |
| DMAA_DMAL0_CH1_SRC_BANK_ADDR[1:0]  | Output | DMAC_DMAL0 Ch1 bank address control pin (for the source)      |
| DMAA_DMAL0_CH1_DST_BANK_ADDR[1:0]  | Output | DMAC_DMAL0 Ch1 bank address control pin (for the destination) |
| DMAA_DMAL0_CH1_DESC_BANK_ADDR[1:0] | Output | DMAC_DMAL0 Ch1 bank address control pin (for the descriptor)  |
| DMAA_DMAL0_CH2_SRC_BANK_ADDR[1:0]  | Output | DMAC_DMAL0 Ch2 bank address control pin (for the source)      |
| DMAA_DMAL0_CH2_DST_BANK_ADDR[1:0]  | Output | DMAC_DMAL0 Ch2 bank address control pin (for the destination) |
| DMAA_DMAL0_CH2_DESC_BANK_ADDR[1:0] | Output | DMAC_DMAL0 Ch2 bank address control pin (for the descriptor)  |
| DMAA_DMAL0_CH3_SRC_BANK_ADDR[1:0]  | Output | DMAC_DMAL0 Ch3 bank address control pin (for the source)      |
| DMAA_DMAL0_CH3_DST_BANK_ADDR[1:0]  | Output | DMAC_DMAL0 Ch3 bank address control pin (for the destination) |
| DMAA_DMAL0_CH3_DESC_BANK_ADDR[1:0] | Output | DMAC_DMAL0 Ch3 bank address control pin (for the descriptor)  |
| DMAA_DMAL0_CH4_SRC_BANK_ADDR[1:0]  | Output | DMAC_DMAL0 Ch4 bank address control pin (for the source)      |
| DMAA_DMAL0_CH4_DST_BANK_ADDR[1:0]  | Output | DMAC_DMAL0 Ch4 bank address control pin (for the destination) |
| DMAA_DMAL0_CH4_DESC_BANK_ADDR[1:0] | Output | DMAC_DMAL0 Ch4 bank address control pin (for the descriptor)  |
| DMAA_DMAL0_CH5_SRC_BANK_ADDR[1:0]  | Output | DMAC_DMAL0 Ch5 bank address control pin (for the source)      |
| DMAA_DMAL0_CH5_DST_BANK_ADDR[1:0]  | Output | DMAC_DMAL0 Ch5 bank address control pin (for the destination) |
| DMAA_DMAL0_CH5_DESC_BANK_ADDR[1:0] | Output | DMAC_DMAL0 Ch5 bank address control pin (for the descriptor)  |
| DMAA_DMAL0_CH6_SRC_BANK_ADDR[1:0]  | Output | DMAC_DMAL0 Ch6 bank address control pin (for the source)      |
| DMAA_DMAL0_CH6_DST_BANK_ADDR[1:0]  | Output | DMAC_DMAL0 Ch6 bank address control pin (for the destination) |
| DMAA_DMAL0_CH6_DESC_BANK_ADDR[1:0] | Output | DMAC_DMAL0 Ch6 bank address control pin (for the descriptor)  |
| DMAA_DMAL0_CH7_SRC_BANK_ADDR[1:0]  | Output | DMAC_DMAL0 Ch7 bank address control pin (for the source)      |
| DMAA_DMAL0_CH7_DST_BANK_ADDR[1:0]  | Output | DMAC_DMAL0 Ch7 bank address control pin (for the destination) |
| DMAA_DMAL0_CH7_DESC_BANK_ADDR[1:0] | Output | DMAC_DMAL0 Ch7 bank address control pin (for the descriptor)  |

### 49.2.1.2 List of DMAC DMAC1 Bank Address Pins

**Table 49.2-2** lists the internal pins (bank address pins for DMAC DMAC1).

Table 49.2-2 List of Internal Pins

| Pin Name                           | I/O    | Function                                                      |
|------------------------------------|--------|---------------------------------------------------------------|
| DMAC DMAC1 Bank Address Signals    |        |                                                               |
| DMAA_DMAL1_CH0_SRC_BANK_ADDR[1:0]  | Output | DMAC_DMAL1 Ch0 bank address control pin (for the source)      |
| DMAA_DMAL1_CH0_DST_BANK_ADDR[1:0]  | Output | DMAC_DMAL1 Ch0 bank address control pin (for the destination) |
| DMAA_DMAL1_CH0_DESC_BANK_ADDR[1:0] | Output | DMAC_DMAL1 Ch0 bank address control pin (for the descriptor)  |
| DMAA_DMAL1_CH1_SRC_BANK_ADDR[1:0]  | Output | DMAC_DMAL1 Ch1 bank address control pin (for the source)      |
| DMAA_DMAL1_CH1_DST_BANK_ADDR[1:0]  | Output | DMAC_DMAL1 Ch1 bank address control pin (for the destination) |
| DMAA_DMAL1_CH1_DESC_BANK_ADDR[1:0] | Output | DMAC_DMAL1 Ch1 bank address control pin (for the descriptor)  |
| DMAA_DMAL1_CH2_SRC_BANK_ADDR[1:0]  | Output | DMAC_DMAL1 Ch2 bank address control pin (for the source)      |
| DMAA_DMAL1_CH2_DST_BANK_ADDR[1:0]  | Output | DMAC_DMAL1 Ch2 bank address control pin (for the destination) |
| DMAA_DMAL1_CH2_DESC_BANK_ADDR[1:0] | Output | DMAC_DMAL1 Ch2 bank address control pin (for the descriptor)  |
| DMAA_DMAL1_CH3_SRC_BANK_ADDR[1:0]  | Output | DMAC_DMAL1 Ch3 bank address control pin (for the source)      |
| DMAA_DMAL1_CH3_DST_BANK_ADDR[1:0]  | Output | DMAC_DMAL1 Ch3 bank address control pin (for the destination) |
| DMAA_DMAL1_CH3_DESC_BANK_ADDR[1:0] | Output | DMAC_DMAL1 Ch3 bank address control pin (for the descriptor)  |
| DMAA_DMAL1_CH4_SRC_BANK_ADDR[1:0]  | Output | DMAC_DMAL1 Ch4 bank address control pin (for the source)      |
| DMAA_DMAL1_CH4_DST_BANK_ADDR[1:0]  | Output | DMAC_DMAL1 Ch4 bank address control pin (for the destination) |
| DMAA_DMAL1_CH4_DESC_BANK_ADDR[1:0] | Output | DMAC_DMAL1 Ch4 bank address control pin (for the descriptor)  |
| DMAA_DMAL1_CH5_SRC_BANK_ADDR[1:0]  | Output | DMAC_DMAL1 Ch5 bank address control pin (for the source)      |
| DMAA_DMAL1_CH5_DST_BANK_ADDR[1:0]  | Output | DMAC_DMAL1 Ch5 bank address control pin (for the destination) |
| DMAA_DMAL1_CH5_DESC_BANK_ADDR[1:0] | Output | DMAC_DMAL1 Ch5 bank address control pin (for the descriptor)  |
| DMAA_DMAL1_CH6_SRC_BANK_ADDR[1:0]  | Output | DMAC_DMAL1 Ch6 bank address control pin (for the source)      |
| DMAA_DMAL1_CH6_DST_BANK_ADDR[1:0]  | Output | DMAC_DMAL1 Ch6 bank address control pin (for the destination) |
| DMAA_DMAL1_CH6_DESC_BANK_ADDR[1:0] | Output | DMAC_DMAL1 Ch6 bank address control pin (for the descriptor)  |
| DMAA_DMAL1_CH7_SRC_BANK_ADDR[1:0]  | Output | DMAC_DMAL1 Ch7 bank address control pin (for the source)      |
| DMAA_DMAL1_CH7_DST_BANK_ADDR[1:0]  | Output | DMAC_DMAL1 Ch7 bank address control pin (for the destination) |
| DMAA_DMAL1_CH7_DESC_BANK_ADDR[1:0] | Output | DMAC_DMAL1 Ch7 bank address control pin (for the descriptor)  |

### 49.2.1.3 List of Bank Address Pins of IP Modules for ICB

**Table 49.2-3** lists the internal pins (bank address pins of the IP modules for the ICB).

Table 49.2-3 List of Internal Pins

| Pin Name                              | I/O    | Function                                  |
|---------------------------------------|--------|-------------------------------------------|
| Peripheral Block Bank Address Signals |        |                                           |
| EMM_BANK_ADDR[1:0]                    | Output | Bank address control pin for eMMC         |
| SDI0_BANK_ADDR[1:0]                   | Output | Bank address control pin for SDI0         |
| SDI1_BANK_ADDR[1:0]                   | Output | Bank address control pin for SDI1         |
| USB_M0_BANK_ADDR[1:0]                 | Output | Bank address control pin for USB Host     |
| USB_M1_BANK_ADDR[1:0]                 | Output | Bank address control pin for USB Function |
| PCI_BANK_ADDR[1:0]                    | Output | Bank address control pin for PCIe         |
| ETH0_BANK_ADDR[1:0]                   | Output | Bank address control pin for ETHER        |
| GRP_BANK_ADDR[1:0]                    | Output | Bank address control pin for GRP          |
| VCD_BANK_ADDR[1:0]                    | Output | Bank address control pin for VCD          |
| DRPA_M0_BANK_ADDR[1:0]                | Output | Bank address control pin for DRP-AI M0    |
| DRPA_M1_BANK_ADDR[1:0]                | Output | Bank address control pin for DRP-AI M1    |
| DRPA_M2_BANK_ADDR[1:0]                | Output | Bank address control pin for DRP-AI M2    |
| DRPA_M3_BANK_ADDR[1:0]                | Output | Bank address control pin for DRP-AI M3    |

### 49.2.1.4 I/F Pins for ICB

**Table 49.2-4** lists the internal pins (for the ICB).

Table 49.2-4 List of Internal Pins

| Pin Name                          | I/O    | Function                                  |
|-----------------------------------|--------|-------------------------------------------|
| ETH AxCACHE[1] Signals            |        |                                           |
| ETH0_ARCACHE_1                    | Output | AR Ch cacheable bit control pin for ETHER |
| ETH0_AWCACHE_1                    | Output | AR Ch cacheable bit control pin for ETHER |
| ICB Observability Control Signals |        |                                           |
| ICB_OBS_SUSP[8:0]                 | Output | OBS counting stop control pin             |

### 49.2.1.5 List of I/F Pins with PCIe

**Table 49.2-5** lists the internal pins (I/F pins with the PCIe).

Table 49.2-5 List of Internal Pins (1/2)

| Pin Name                | I/O    | Function                                                                                                                                                                  |
|-------------------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PCIe I/F Signal (1/2)   |        |                                                                                                                                                                           |
| FLR_REQ[1:0]            | Input  | Function Level Reset request<br>Notifying the FLR request from the root<br>Bit 0: Function 0<br>Bit 1: Function 1                                                         |
| FLR_RESET[1:0]          | Output | Reset input for the Function Level Reset execution instruction<br>Notifying the root of execution of FLR in response to FLR_REQ<br>Bit 0: Function 0<br>Bit 1: Function 1 |
| INTX_EP_F0              | Output | INTX signal for function 0                                                                                                                                                |
| INTX_EP_F1              | Output | INTX signal for function 1                                                                                                                                                |
| UI_EXTMSI_VAL0          | Output | MSI interrupt notification pin                                                                                                                                            |
| UI_EXTMSI_VAL1          | Output | MSI interrupt notification pin                                                                                                                                            |
| UI_EXTMSI_VAL2          | Output | MSI interrupt notification pin                                                                                                                                            |
| UI_EXTMSI_VAL3          | Output | MSI interrupt notification pin                                                                                                                                            |
| UI_EXTMSI_VAL4          | Output | MSI interrupt notification pin                                                                                                                                            |
| UI_EXTMSI_VEC0[4:0]     | Output | MSI interrupt vector specification pin                                                                                                                                    |
| UI_EXTMSI_VEC1[4:0]     | Output | MSI interrupt vector specification pin                                                                                                                                    |
| UI_EXTMSI_VEC2[4:0]     | Output | MSI interrupt vector specification pin                                                                                                                                    |
| UI_EXTMSI_VEC3[4:0]     | Output | MSI interrupt vector specification pin                                                                                                                                    |
| UI_EXTMSI_VEC4[4:0]     | Output | MSI interrupt vector specification pin                                                                                                                                    |
| UI_EXTMSI_FUNC0[2:0]    | Output | MSI interrupt function number specification pin                                                                                                                           |
| UI_EXTMSI_FUNC1[2:0]    | Output | MSI interrupt function number specification pin                                                                                                                           |
| UI_EXTMSI_FUNC2[2:0]    | Output | MSI interrupt function number specification pin                                                                                                                           |
| UI_EXTMSI_FUNC3[2:0]    | Output | MSI interrupt function number specification pin                                                                                                                           |
| UI_EXTMSI_FUNC4[2:0]    | Output | MSI interrupt function number specification pin                                                                                                                           |
| ALLOW_ENTER_L1          | Output | ASPM L1 state transition enable<br>0: Transition is inhibited.<br>1: Transition is enabled.                                                                               |
| PME_TIM                 | Output | PM_PME message transmission clock<br>(does not have a clock attribute)                                                                                                    |
| TURN_OFF_EVENT          | Input  | PME_Turn_Off message reception notification pin                                                                                                                           |
| TURN_OFF_EVENT_ACK      | Output | Turn off preparation completion notification pin                                                                                                                          |
| D3_EVENT_F0             | Input  | Non-D0 state transition request reception notification pin<br>(for function 0)                                                                                            |
| D3_EVENT_F1             | Input  | Non-D0 state transition request reception notification pin<br>(for function 1)                                                                                            |
| D3_EVENT_ACK_F0         | Output | Non-D0 state transition preparation completion notification pin<br>(for function 0)                                                                                       |
| D3_EVENT_ACK_F1         | Output | Non-D0 state transition preparation completion notification pin<br>(for function 1)                                                                                       |
| CFG_PMCSR_PME_STATUS_F0 | Output | Power management event setting pin<br>(for function 0)                                                                                                                    |

Table 49.2-5 List of Internal Pins (2/2)

| Pin Name                           | I/O    | Function                                                                                     |

### 49.2.1.6 RAMA-ECC Initialization Control Pins

**Table 49.2-6** lists the internal pins (I/F pins with RAMA).

Table 49.2-6 List of Internal Pins

| Pin Name                            | I/O    | Function                                                                                                     |
|-------------------------------------|--------|--------------------------------------------------------------------------------------------------------------|
| RAMA ECC Initialize Control Signals |        |                                                                                                              |
| RAMA_VECCEN                         | Output | Switches enabling and disabling of error correction by the ECC.<br>0: ECC is disabled.<br>1: ECC is enabled. |
| RAMA_INIT                           | Output | RAMA ECC code area initialization control                                                                    |
| RAMA_INIT_END                       | Input  | RAMA ECC code area initialization end flag                                                                   |

### 49.2.1.7 MD0 to MD7 Pins

**Table 49.2-7** lists the internal pins (MD0 to MD7 pins).

Table 49.2-7 List of Internal Pins

| Pin Name     | I/O   | Function                           |
|--------------|-------|------------------------------------|
| Mode Signals |       |                                    |
| MD0          | Input | Boot device selection [0]          |
| MD1          | Input | Boot device selection [1]          |
| MD2          | Input | Boot device selection [2]          |
| MD3          | Input | Boot device write interface select |
| MD4          | Input | Boot mode selection [0] (reserved) |
| MD5          | Input | Boot mode selection [1] (reserved) |
| MD6          | Input | Boot mode selection [2]            |
| MD7          | Input | Boot mode selection [3] (reserved) |

#### 49.2.1.8 List of WDT-I/F Pins

**Table 49.2-8** lists the internal pins (WDT-I/F pins).

Table 49.2-8 List of Internal Pins

| Pin Name                         | I/O    | Function                                                                                                          |
|----------------------------------|--------|-------------------------------------------------------------------------------------------------------------------|
| WDT Counter Stop Control Signals |        |                                                                                                                   |
| CST_HLTDBG[1:0]                  | Input  | Trigger Pin for WDT (input from CST)<br>0: Counting by the WDT is possible.<br>1: Stops counting by the WDT.      |
| WDT_CNTSTOP[1:0]                 | Output | WDT Counting Stop Control (output to WDT)<br>0: Counting by the WDT is possible.<br>1: Stops counting by the WDT. |

The following describes the internal pin functions of the SYS.

## 49.2.2 Bank Address Switching Pins

### 49.2.2.1 Bank Addresses for DMAC

These pins are connected to the DMAC and extend the area which can be accessed by the instruction from the SYS from 32 bits (4 GB) to 34 bits (16 GB).

#### **DMAA\_DMAC0\_CHn\_SRC\_BANK\_ADDR[1:0]**

DMAC DMAC0 Channel n Source Bank Address

*Note:* n = 0 to 7

#### **DMAA\_DMAC0\_CHn\_DST\_BANK\_ADDR[1:0]**

DMAC DMAC0 Channel n Destination Bank Address

*Note:* n = 0 to 7

#### **DMAA\_DMAC0\_CHn\_DESC\_BANK\_ADDR[1:0]**

DMAC DMAC0 Channel n Descriptor Bank Address

*Note:* n = 0 to 7

#### **DMAA\_DMAC1\_CHn\_SRC\_BANK\_ADDR[1:0]**

DMAC DMAC1 Channel n Source Bank Address

*Note:* n = 0 to 7

#### **DMAA\_DMAC1\_CHn\_DST\_BANK\_ADDR[1:0]**

DMAC DMAC1 Channel n Destination Bank Address

*Note:* n = 0 to 7

#### **DMAA\_DMAC1\_CHn\_DESC\_BANK\_ADDR[1:0]**

DMAC DMAC1 Channel n Descriptor Bank Address

*Note:* n = 0 to 7

### 49.2.2.2 Bank Addresses for ICB

#### **EMM\_BANK\_ADDR[1:0]**

eMMC Bank Address

This pin is connected to the ICB and extends the area which can be accessed by eMMC from 32 bits (4 GB) to 34 bits (16 GB).

#### **SDI0\_BANK\_ADDR[1:0]**

SDI0 Bank Address

This pin is connected to the ICB and extends the area which can be accessed by SDI0 from 32 bits (4 GB) to 34 bits (16 GB).

#### **SDI1\_BANK\_ADDR[1:0]**

SDI1 Bank Address

This pin is connected to the ICB and extends the area which can be accessed by SDI1 from 32 bits (4 GB) to 34 bits (16 GB).

#### **USB\_M0\_BANK\_ADDR[1:0]**

USB Host Bank Address

This pin is connected to the ICB and extends the area which can be accessed by a USB host from 32 bits (4 GB) to 34 bits (16 GB).

#### **USB\_M1\_BANK\_ADDR[1:0]**

USB Peripheral Bank Address

This pin is connected to the ICB and extends the area which can be accessed by a USB peripheral from 32 bits (4 GB) to 34 bits (16 GB).

#### **PCI\_BANK\_ADDR[1:0]**

PCIe Bank Address

This pin is connected to the ICB and extends the area which can be accessed by the PCIe from 32 bits (4 GB) to 34 bits (16 GB).

#### **ETH0\_BANK\_ADDR[1:0]**

ETHER Bank Address

This pin is connected to the ICB and extends the area which can be accessed by the ETHER from 32 bits (4 GB) to 34 bits (16 GB).

#### **GRP\_BANK\_ADDR[1:0]**

GRP Bank Address

This pin is connected to the ICB and extends the area which can be accessed by the GRP from 32 bits (4 GB) to 34 bits (16 GB).

#### **VCD\_BANK\_ADDR[1:0]**

VCD Bank Address

This pin is connected to the ICB and extends the area which can be accessed by the VCD from 32 bits (4 GB) to 34 bits (16 GB).

**DRPA\_M0\_BANK\_ADDR[1:0]**

DRP-AI M0 Bank Address

This pin is connected to the ICB and extends the area which can be accessed by DRP-AI M0 from 32 bits (4 GB) to 34 bits (16 GB).

**DRPA\_M1\_BANK\_ADDR[1:0]**

DRP-AI M1 Bank Address

This pin is connected to the ICB and extends the area which can be accessed by DRP-AI M1 from 32 bits (4 GB) to 34 bits (16 GB).

**DRPA\_M2\_BANK\_ADDR[1:0]**

DRP-AI M2 Bank Address

This pin is connected to the ICB and extends the area which can be accessed by DRP-AI M2 from 32 bits (4 GB) to 34 bits (16 GB).

**DRPA\_M3\_BANK\_ADDR[1:0]**

DRP-AI M3 Bank Address

This pin is connected to the ICB and extends the area which can be accessed by DRP-AI M3 from 32 bits (4 GB) to 34 bits (16 GB).

### 49.2.3 I/F Pins for ICB

#### 49.2.3.1 ETH AxCACHE[1]

##### ETH0\_ARCACHE\_1

ETHER AR Channel Cacheable Bit Control Pin

This pin is connected to the ICB and controls ARCACHE[1] (cacheable bit) for the AR channel of the ETHER.

##### ETH0\_AWCACHE\_1

ETHER AW Channel Cacheable Bit Control Pin

This pin is connected to the ICB and controls AWCACHE[1] (cacheable bit) for the AW channel of the ETHER.

#### 49.2.3.2 Observability

##### ICB\_OBS\_SUSP[8:0]

ICB Observability Counting Stop Pin

Bit 8: StatSuspend for Scheduler Output Ports

Bit 7: StatSuspend for Scheduler Input Port #8

Bit 6: StatSuspend for Scheduler Input Port #7

Bit 5: StatSuspend for Scheduler Input Port #6

Bit 4: StatSuspend for Scheduler Input Port #5

Bit 3: StatSuspend for Scheduler Input Port #4

Bit 2: StatSuspend for Scheduler Input Port #3

Bit 1: StatSuspend for Scheduler Input Port #2

Bit 0: StatSuspend for Scheduler Input Port #1

#### 49.2.4 I/F Pins with PCIe

The following pins are connected to the pins with the same name as the PCIe unit.

For details of the pin functions, refer to the section of PCIe.

##### 49.2.4.1 Function Level Reset

###### FLR\_REQ[1:0]

Function Level Reset request notification pin supplied from the PCIe (active high) (for endpoint).

Each bit corresponds to the function number.

###### FLR\_RESET[1:0]

Reset pin for the Function Level Reset execution instruction for output to the PCIe (active high) (for endpoint).

Each bit corresponds to the function number.

##### 49.2.4.2 Interrupt Control Pins

These are legacy interrupt and Assert\_INTx/Deassert\_INTx control pins and MSI transmission pins.

###### INTX\_EP\_F0

INTx interrupt signal pin (for endpoint) for output to the PCIe for function 0.

###### INTX\_EP\_F1

INTx interrupt signal pin (for endpoint) for output to the PCIe for function 1.

###### UI\_EXTMSI\_VAL0/1/2/3/4

Interrupt notification pins for output to the PCIe (for endpoint).

These are output pins for issuing an MSI specified by the user to the other-party RC.

###### UI\_EXTMSI\_VEC0/1/2/3/4 [4:0]

Interrupt vector specification pin for output to the PCIe (for endpoint).

Specifies the vector section of the MSI to be issued by UI\_EXTMSI\_VAL.

###### UI\_EXTMSI\_FUNC0/1/2/3/4 [2:0]

Interrupt function number specification pin for output to the PCIe (for endpoint).

Specifies the function number of the MSI to be issued by UI\_EXTMSI\_VAL.

### 49.2.4.3 Power Management Control (PMC) Pins

#### **ALLOW\_ENTER\_L1**

ASPM L1 state enable setting pin for output to the PCIe.

#### **PME\_TIM**

PM\_PME message clock pin for output to the PCIe (only for endpoint).

#### **TURN\_OFF\_EVENT**

PME\_Turn\_Off message reception flag pin supplied from the PCIe (only for endpoint).

#### **TURN\_OFF\_EVENT\_ACK**

Acknowledge pin for output to the PCIe (only for endpoint).

#### **D3\_EVENT\_F0**

Non-D0 state transition request reception pin supplied from the PCIe (only for endpoint) for function 0.

#### **D3\_EVENT\_F1**

Non-D0 state transition request reception pin supplied from the PCIe (only for endpoint) for function 1.

#### **D3\_EVENT\_ACK\_F0**

Acknowledge pin for output to the PCIe (only for endpoint) for function 0.

#### **D3\_EVENT\_ACK\_F1**

Acknowledge pin for output to the PCIe (only for endpoint) for function 1.

#### **CFG\_PMCSR\_PME\_STATUS\_F0**

Power management event setting pin for output to the PCIe (only for endpoint) for function 0.

#### **CFG\_PMCSR\_PME\_STATUS\_F1**

Power management event setting pin for output to the PCIe (only for endpoint) for function 1.

#### **CFG\_PMCSR\_PME\_STATUS\_WRITECLEAR\_F0**

PME\_STATUS clearing pin supplied from the PCIe (only for endpoint) for function 0.

#### **CFG\_PMCSR\_PME\_STATUS\_WRITECLEAR\_F1**

PME\_STATUS clearing pin supplied from the PCIe (only for endpoint) for function 1.

#### 49.2.4.4 Macro Control Pins

##### MODE\_PORT

Device type setting pin for output to the PCIe.

This pin is for setting operation as an endpoint or root complex.

- 0: Endpoint (upstream port)
- 1: Root complex (downstream port)

##### CAUTION

Since the MODE\_PORT pin is for determining the operating mode of the PCIe, changing the setting during PCIe operation is prohibited.

Be sure to make the setting during the PCIe reset period.

##### MODE\_PORT\_ENABLE\_B

Macro off mode setting pin for output to the PCIe.

This is a disable pin for the macro including the SerDes hard macro.

By asserting this signal, input of the reference clock is disabled. This allows a minimum power consumption. The signal is fixed to 0 in normal operation.

- 0: Normal operation
- 1: Macro off

##### CAUTION

The macro off setting of the PCIe unit can also be made from a register of the PCIe.

When using the setting from a register of the PCIe, fix the value to 0.

##### PCI\_LANE\_SEL[1:0]

Lane setting pin for output to the PCIe when accessing PMA registers.

- 0x: Lane 0
- 1x: Lane 1
- (x: Don't care)

### 49.2.5 RAMA-ECC Initialization Control Pins

#### **RAMA\_VECCEN**

This pin switches enabling and disabling of error correction by the ECC.

- 0: ECC is disabled.
- 1: ECC is enabled.

For details of this pin function, refer to the section of RAMA.

#### **RAMA\_INIT/RAMA\_INIT\_END**

When RAMA\_INIT is driven from low to high and CLK is input, RAMA\_INIT\_END changes from 0 to 1, and the data in the internal RAM and the whole area of the ECC code are initialized.

For details of this pin function, refer to the section of RAMA.

- **RAMA\_INIT**
  - 0: Initialization is disabled.
  - 1: Initialization is enabled.
- **RAMA\_INIT\_END**
  - 0: Initialization is in progress (this setting only has effect while RAMA\_INIT is 1).
  - 1: Initialization is completed.

### 49.2.6 MD0 to MD7 Pins

#### **MD2 to MD0**

Boot device selection pins

#### **MD3**

Boot device write interface select

#### **MD4 and MD5**

Boot mode switching pins (reserved)

#### **MD6**

Boot mode switching pin

#### **MD7**

Boot mode switching pin (reserved)

### 49.2.7 WDT Counting Stop Control Pins

#### **CST\_HLTDBG[1:0]**

Counting Control input Pin for the WDT from the CST.

This pin controls counting by the WDT.

0: Counting by the WDT is possible.

1: Stops counting by the WDT.

#### **WDT\_CNTSTOP[1:0]**

Counting Control Pin for the WDT

This pin outputs the logical OR of the values of the signal CST\_HLTDBG[1:0] from the CST and the internal register WDT\_CNTSTOP of the SYS.

0: Counting by the WDT is possible.

1: Stops counting by the WDT.

## 49.3 Register Descriptions

The following lists the registers of the SYS.

For the register base address (<SYS\_S0\_base >), see the section of Address Map.

### 49.3.1 List of Registers

The registers of the SYS are listed below.

#### 49.3.1.1 List of Bank Address Switching Registers

**Table 49.3-1** lists the bank address switching registers of the SYS.

Table 49.3-1 List of SYS Registers

| Offset Address                                            | Register Name                                    | Abbreviation        | Initial Value | Access Unit (bits) |
|-----------------------------------------------------------|--------------------------------------------------|---------------------|---------------|--------------------|
| DMAC DMAC0 Bank Address Control Registers 000h-00Ch       |                                                  |                     |               |                    |
| 000h                                                      | DMAA_DMCA0 Ch0&Ch1 Bank Address Control Register | SYS_DMAA0_CH01_BANK | 0000_0000h    | 32                 |
| 004h                                                      | DMAA_DMCA0 Ch2&Ch3 Bank Address Control Register | SYS_DMAA0_CH23_BANK | 0000_0000h    | 32                 |
| 008h                                                      | DMAA_DMCA0 Ch4&Ch5 Bank Address Control Register | SYS_DMAA0_CH45_BANK | 0000_0000h    | 32                 |
| 00Ch                                                      | DMAA_DMCA0 Ch6&Ch7 Bank Address Control Register | SYS_DMAA0_CH67_BANK | 0000_0000h    | 32                 |
| DMAC DMAC1 Bank Address Control Registers 010h-01Ch       |                                                  |                     |               |                    |
| 010h                                                      | DMAA_DMCA1 Ch0&Ch1 Bank Address Control Register | SYS_DMAA1_CH01_BANK | 0000_0000h    | 32                 |
| 014h                                                      | DMAA_DMCA1 Ch2&Ch3 Bank Address Control Register | SYS_DMAA1_CH23_BANK | 0000_0000h    | 32                 |
| 018h                                                      | DMAA_DMCA1 Ch4&Ch5 Bank Address Control Register | SYS_DMAA1_CH45_BANK | 0000_0000h    | 32                 |
| 01Ch                                                      | DMAA_DMCA1 Ch6&Ch7 Bank Address Control Register | SYS_DMAA1_CH67_BANK | 0000_0000h    | 32                 |

| 098h-09Ch                            | Reserved                                                                               | —                      | —             | —                  |
| 0A0h                                 | PCI target lane setting register                                                       | PCI_LANE_SEL           | 0000_0000h    | 32                 |
| 0A4h-0FCh                            | Reserved                                                                               | —                      | —             | —                  |

Note 1. This register determines the operating mode of the PCIe (as endpoint or root complex). Changing the setting during PCIe operation is prohibited. Be sure to make the setting during the PCIe reset period.

Note 2. The register values are output after synchronization with the PCI\_ACLK clock. Be sure to supply the PCI\_ACLK clock before setting values in the registers.

Note 3. If the frequency of the PCI\_ACLK clock is 48 MHz or 50 MHz, consecutive writing to the same address is prohibited (read the register value before writing a value again).

### 49.3.1.3 List of Device Status and RAMA Initialization Control Registers

**Table 49.3-3** lists the MD pin monitor register, LSI version register, and RAMA initialization control registers of the SYS.

Table 49.3-3 List of SYS Registers

| Offset Address                                  | Register Name                                         | Abbreviation      | Initial Value | Access Unit (bits) |

### 49.3.2 Register Descriptions

The function description of each register is given below.

#### 49.3.2.1 DMAA\_DMAC0 Ch0&Ch1 Bank Address Control Register (SYS\_DMAA0\_CH01\_BANK)

This register controls the bank addresses of DMAC0 ch. 0 and ch. 1.

Set the BA field to 01b or 00b.

**Access Size:** 32 bits

**Address(es):** <SYS\_S0\_base> + 0000h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30 | 29           | 28   | 27   | 26   | 25   | 24   | 23 | 22 | 21           | 20   | 19   | 18   | 17   | 16   |

### 49.3.2.5 DMAA\_DMCA1 Ch0&Ch1 Bank Address Control Register (SYS\_DMAA1\_CH01\_BANK)

This register controls the bank addresses of DMAC1 ch. 0 and ch. 1.

Set the BA field to 01b or 00b.

**Access Size:** 32 bits

**Address(es):** <SYS\_S0\_base> + 0010h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30 | 29           | 28   | 27   | 26   | 25   | 24   | 23 | 22 | 21   | 20   | 19           | 18   | 17   | 16   |

### 49.3.2.8 DMAA\_DMCA1 Ch6&Ch7 Bank Address Control Register (SYS\_DMAA1\_CH67\_BANK)

This register controls the bank addresses of DMAC1 ch. 6 and ch. 7.

Set the BA field to 01b or 00b.

**Access Size:** 32 bits

**Address(es):** <SYS\_S0\_base> + 001Ch

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30 | 29           | 28   | 27   | 26   | 25   | 24   | 23 | 22 | 21           | 20   | 19   | 18   | 17   | 16   |

| 15 to 12     | —            | Reserved. These bits are read as 0b.                                                                                                    |
| 11, 10       | BA[11:10]    | Control VCD bank address.                                                                                                               |
| 9, 8         | —            | Reserved. These bits are read as 0b.                                                                                                    |
| 7, 6         | BA[07:06]    | Control GRP bank address.                                                                                                               |
| 5 to 2       | —            | Reserved. These bits are read as 0b.                                                                                                    |
| 1, 0         | BA[01:00]    | Control ETHER bank address.                                                                                                             |

### 49.3.2.11 DRP Bank Address Control Register (SYS\_DRP\_BANK)

This register controls the bank addresses of DRP for ICB.

Set the BA field to 01b or 00b.

**Access Size:** 32 bits

**Address(es):** <SYS\_S0\_base> + 0038h

**Initial Value:** 0000\_0000h

|               |    |    |    |    |    |    |      |      |              |      |           |      |           |      |           |      |

Table 49.3-18 SYS\_DRP\_BANK Register Contents

| Bit Position | Bit Name     | Description                                                                                                                                       |
|--------------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 26     | —            | Reserved. These bits are read as 0b.                                                                                                              |
| 25, 24       | —            | Reserved. These bits are read as 0b. The write value should always be 0b.                                                                         |
| 23 to 16     | BA_WE[07:00] | Enables write to BA[07:00].<br>Write only. These bits are read as 0b.<br>0b: Invalid write to BA[07:00]<br>1b: Valid write to BA[07:00]           |
| 15 to 10     | —            | Reserved. These bits are read as 0b.                                                                                                              |
| 9, 8         | —            | Reserved. When read, the value read is undefined. Since these bits are for use with the ISP support package, writing to these bits is prohibited. |
| 7, 6         | BA[07:06]    | Control DRP-AI M3 bank address.                                                                                                                   |
| 5, 4         | BA[05:04]    | Control DRP-AI M2 bank address.                                                                                                                   |
| 3, 2         | BA[03:02]    | Control DRP-AI M1 bank address.                                                                                                                   |
| 1, 0         | BA[01:00]    | Control DRP-AI M0 bank address.                                                                                                                   |

49.3.2.12 PCI Function Level Reset Request Confirmation Register (PCI\_FLR\_REQ)

This register is for monitoring to check the FLR\_REQ pin (Function Level Reset (FLR) request) supplied from the PCIe.

Writing to this register has no effect.

Access Size: 32 bits  
Address(es): <SYS\_S0\_base> + 0040h  
Initial Value: 0000\_000xh (The initial value of the LSB two bits depends on the state of the FLR request signal.)

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |         |    |

Table 49.3-20 PCI\_FLR\_RST Register Contents

| Bit Position | Bit Name     | Description                                                                                                             |
|--------------|--------------|-------------------------------------------------------------------------------------------------------------------------|
| 31 to 2      | Reserved     | These bits are always read as 0.                                                                                        |
| 1            | FLR_RESET[1] | Reset output for the Function Level Reset execution instruction (function 1)<br>0b: Release from the reset<br>1b: Reset |
| 0            | FLR_RESET[0] | Reset output for the Function Level Reset execution instruction (function 0)<br>0b: Release from the reset<br>1b: Reset |

NOTE

The value of this register is output from the FLR\_RESET[1:0] pin after synchronization with the AXI clock (PCI\_ACLK) of the PCIe. Therefore, the register value is not reflected in the FLR\_RESET[1:0] pin while the AXI clock of the PCIe is stopped. It is reflected in the FLR\_RESET[1:0] pin after operation of the AXI clock of the PCIe.

### 49.3.2.14 PCI INTX Control Register (PCI\_INTX\_EP)

This register controls the INTX pins (INTX\_EP\_F0 and INTX\_EP\_F1) for output to the PCIe.

**Access Size:** 32 bits

**Address(es):** <SYS\_S0\_base> + 0048h

**Initial Value:** 0000\_0000h

|               |    |    |    |    |    |    |    |    |    |    |    |             |    |    |    |             |

Table 49.3-21 PCI\_INTX\_EP Register Contents

| Bit Position | Bit Name | Description                        |
|--------------|----------|------------------------------------|
| 31 to 5      | Reserved | These bits are always read as 0b.  |
| 4            | INTX_F1  | INTX output control for function 1 |
| 3 to 1       | Reserved | These bits are always read as 0b.  |
| 0            | INTX_F0  | INTX output control for function 0 |

### 49.3.2.15 PCI MSI Issuing Register (PCI\_EXTMSI\_VAL)

This register controls the MSI interrupt notification pins (UI\_EXTMSI\_VAL0/1/2/3/4) for output to the PCIe.

**Access Size:** 32 bits

**Address(es):** <SYS\_S0\_base> + 004Ch

**Initial Value:** 0000\_0000h

|               |    |    |    |      |    |    |    |      |    |    |    |      |    |    |    |      |

Table 49.3-22 PCI\_EXTMSI\_VAL Register Contents

| Bit Position | Bit Name | Description                                                                          |
|--------------|----------|--------------------------------------------------------------------------------------|
| 31 to 17     | Reserved | These bits are always read as 0b.                                                    |
| 16           | VAL4     | MSI interrupt notification 4<br>Controls the output value on the UI_EXTMSI_VAL4 pin. |
| 15 to 13     | Reserved | These bits are always read as 0b.                                                    |
| 12           | VAL3     | MSI interrupt notification 3<br>Controls the output value on the UI_EXTMSI_VAL3 pin. |
| 11 to 9      | Reserved | These bits are always read as 0b.                                                    |
| 8            | VAL2     | MSI interrupt notification 2<br>Controls the output value on the UI_EXTMSI_VAL2 pin. |
| 7 to 5       | Reserved | These bits are always read as 0b.                                                    |
| 4            | VAL1     | MSI interrupt notification 1<br>Controls the output value on the UI_EXTMSI_VAL1 pin. |
| 3 to 1       | Reserved | These bits are always read as 0b.                                                    |
| 0            | VAL0     | MSI interrupt notification 0<br>Controls the output value on the UI_EXTMSI_VAL0 pin. |

#### NOTE

The value of this register is output from the UI\_EXTMSI\_VAL4/3/2/1/0 pin after synchronization with the AXI clock (PCI\_ACLK) of the PCIe. Therefore, the register value is not reflected in the UI\_EXTMSI\_VAL4/3/2/1/0 pin while the AXI clock of the PCIe is stopped. It is reflected in the UI\_EXTMSI\_VAL4/3/2/1/0 pin after operation of the AXI clock of the PCIe.

### 49.3.2.16 PCI Issued MSI Setting Register 0 (PCI\_EXTMSI\_SET0)

This register controls the pins for UI\_EXTMSI\_VAL0 (UI\_EXTMSI\_VEC0 and UI\_EXTMSI\_FUNC0) for output to the PCIe.

#### CAUTION

The value of this register is output from the UI\_EXTMSI\_FUNC0[2:0] or UI\_EXTMSI\_VEC0[4:0] pin after synchronization with the AXI clock (PCI\_ACLK) of the PCIe. Therefore, writing to this register is prohibited while PCI\_ACLK is stopped. When writing to this register, only do so while PCI\_ACLK is operating.

### 49.3.2.17 PCI Issued MSI Setting Register 1 (PCI\_EXTMSI\_SET1)

This register controls the pins for UI\_EXTMSI\_VAL1 (UI\_EXTMSI\_VEC1 and UI\_EXTMSI\_FUNC1) for output to the PCIe.

#### CAUTION

The value of this register is output from the UI\_EXTMSI\_FUNC1[2:0] or UI\_EXTMSI\_VEC1[4:0] pin after synchronization with the AXI clock (PCI\_ACLK) of the PCIe. Therefore, writing to this register is prohibited while PCI\_ACLK is stopped. When writing to this register, only do so while PCI\_ACLK is operating.

### 49.3.2.18 PCI Issued MSI Setting Register 2 (PCI\_EXTMSI\_SET2)

This register controls the pins for UI\_EXTMSI\_VAL2 (UI\_EXTMSI\_VEC2 and UI\_EXTMSI\_FUNC2) for output to the PCIe.

#### CAUTION

The value of this register is output from the UI\_EXTMSI\_FUNC2[2:0] or UI\_EXTMSI\_VEC2[4:0] pin after synchronization with the AXI clock (PCI\_ACLK) of the PCIe. Therefore, writing to this register is prohibited while PCI\_ACLK is stopped. When writing to this register, only do so while PCI\_ACLK is operating.

### 49.3.2.19 PCI Issued MSI Setting Register 3 (PCI\_EXTMSI\_SET3)

This register controls the pins for UI\_EXTMSI\_VAL3 (UI\_EXTMSI\_VEC3 and UI\_EXTMSI\_FUNC3) for output to the PCIe.

#### CAUTION

The value of this register is output from the UI\_EXTMSI\_FUNC3[2:0] or UI\_EXTMSI\_VEC3[4:0] pin after synchronization with the AXI clock (PCI\_ACLK) of the PCIe. Therefore, writing to this register is prohibited while PCI\_ACLK is stopped. When writing to this register, only do so while PCI\_ACLK is operating.

#### 49.3.2.20 PCI Issued MSI Setting Register 4 (PCI\_EXTMSI\_SET4)

This register controls the pins for UI\_EXTMSI\_VAL4 (UI\_EXTMSI\_VEC4 and UI\_EXTMSI\_FUNC4) for output to the PCIe.

##### CAUTION

The value of this register is output from the UI\_EXTMSI\_FUNC4[2:0] or UI\_EXTMSI\_VEC4[4:0] pin after synchronization with the AXI clock (PCI\_ACLK) of the PCIe. Therefore, writing to this register is prohibited while PCI\_ACLK is stopped. When writing to this register, only do so while PCI\_ACLK is operating.

49.3.2.21 PCI ASPM L1 State Transition Enable Register (PCI\_ALLOW\_ENTER\_L1)

This register controls the ASPM L1 state enable setting pin (ALLOW\_ENTER\_L1) for output to the PCIe.

Access Size: 32 bits  
Address(es): <SYS\_S0\_base> + 0064h  
Initial Value: 0000\_0000h

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Table 49.3-28 PCI\_ALLOW\_ENTER\_L1 Register Contents

| Bit Position | Bit Name | Description                                                                                                             |
|--------------|----------|-------------------------------------------------------------------------------------------------------------------------|
| 31 to 1      | Reserved | These bits are always read as 0b.                                                                                       |
| 0            | EN       | 0b: Controls transition from ASPM L0 to the ASPM L1 state.<br>1b: Enables transition from ASPM L0 to the ASPM L1 state. |

NOTE

The value of this register is output from the ALLOW\_ENTER\_L1 pin after synchronization with the AXI clock (PCI\_ACLK) of the PCIe. Therefore, the register value is not reflected in the ALLOW\_ENTER\_L1 pin while the AXI clock of the PCIe is stopped. It is reflected in the ALLOW\_ENTER\_L1 pin after operation of the AXI clock of the PCIe.

49.3.2.22 PCI\_PM\_PME Message Transmission Clock Register (PCI\_PME\_TIM)

This register controls the PM\_PME message transmission clock pin (PME\_TIM) for output to the PCIe.

Access Size: 32 bits  
Address(es): <SYS\_S0\_base> + 006Ch  
Initial Value: 0000\_0000h

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| Bit Position | Bit Name | Description                                         |
|--------------|----------|-----------------------------------------------------|
| 31 to 1      | Reserved | These bits are always read as 0b.                   |
| 0            | PME_TIM  | Controls the PM_PME message transmission clock pin. |

49.3.2.23 PCI PME\_Turn\_Off Message Reception Confirmation Register (PCI\_TURN\_OFF\_EVENT)

This register is for monitoring the PME\_Turn\_Off message reception notification flag confirmation pin (TURN\_OFF\_EVENT) supplied from the PCIe.

Writing to this register has no effect.

**Access Size:** 32 bits  
**Address(es):** <SYS\_S0\_base> + 0070h  
**Initial Value:** 0000\_000xh (The initial value of the LSB one bit depends on the PME\_Turn\_Off message reception notification flag.)

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| Bit Position | Bit Name | Description                                      |
|--------------|----------|--------------------------------------------------|
| 31 to 1      | Reserved | These bits are always read as 0b.                |
| 0            | FLG      | PME_Turn_Off message reception notification flag |

49.3.2.24 PCI Turn Off Preparation Completion Register (PCI\_TURN\_OFF\_EVENT\_ACK)

This register controls the turn off preparation completion notification pin (TURN\_OFF\_EVENT\_ACK) for output to the PCIe.

Access Size: 32 bits  
Address(es): <SYS\_S0\_base> + 0074h  
Initial Value: 0000\_0000h

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

Table 49.3-31 PCI\_TURN\_OFF\_EVENT\_ACK Register Contents

| Bit Position | Bit Name | Description                                               |
|--------------|----------|-----------------------------------------------------------|
| 31 to 1      | Reserved | These bits are always read as 0b.                         |
| 0            | ACK      | Notifying the completion of preparation for PME_Turn_Off. |

NOTE

The value of this register is output from the TURN\_OFF\_EVENT\_ACK pin after synchronization with the AXI clock (PCI\_ACLK) of the PCIe. Therefore, the register value is not reflected in the TURN\_OFF\_EVENT\_ACK pin while the AXI clock of the PCIe is stopped. It is reflected in the TURN\_OFF\_EVENT\_ACK pin after operation of the AXI clock of the PCIe.

49.3.2.25 PCI Non-D0 State Transition Request Reception Confirmation Register (PCI\_D3\_EVENT)

This register is for monitoring the non-D0 state transition request reception notification flag confirmation pins ((D3\_EVENT\_F0/1) supplied from the PCIe.

Writing to this register has no effect.

**Access Size:** 32 bits  
**Address(es):** <SYS\_S0\_base> + 0080h  
**Initial Value:** 0000\_00xxh (The initial value of bit 0 and bit 4 depends on the non-D0 state transition request reception notification flag.)

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Table 49.3-33 PCI\_D3\_EVENT\_ACK Register Contents

| Bit Position | Bit Name | Description                                                                |
|--------------|----------|----------------------------------------------------------------------------|
| 31 to 5      | Reserved | These bits are always read as 0b.                                          |
| 4            | F1       | Non-D0 state transition request reception notification flag for function 1 |
| 3 to 1       | Reserved | These bits are always read as 0b.                                          |
| 0            | F0       | Non-D0 state transition request reception notification flag for function 0 |

NOTE

The value of this register is output from the D3\_EVENT\_ACK\_F1/0 pin after synchronization with the AXI clock (PCI\_ACLK) of the PCIe. Therefore, the register value is not reflected in the D3\_EVENT\_ACK\_F1/0 pin while the AXI clock of the PCIe is stopped. It is reflected in the D3\_EVENT\_ACK\_F1/0 pin after operation of the AXI clock of the PCIe.

### 49.3.2.27 PCI PME Assertion Source Notification Register (PCI\_PME\_STS)

This register controls the power management event setting pins (CFG\_PMCSR\_PME\_STATUS\_F0/1) for output to the PCIe.

**Access Size:** 32 bits

**Address(es):** <SYS\_S0\_base> + 0088h

**Initial Value:** 0000\_0000h

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Table 49.3-34 PCI\_PME\_STS Register Contents

| Bit Position | Bit Name | Description                                                     |
|--------------|----------|-----------------------------------------------------------------|
| 31 to 5      | Reserved | These bits are always read as 0b.                               |
| 4            | F1       | Controls the Power Management Event setting pin for function 1. |
| 3 to 1       | Reserved | These bits are always read as 0b.                               |
| 0            | F0       | Controls the Power Management Event setting pin for function 0. |

#### NOTE

The value of this register is output from the CFG\_PMCSR\_PME\_STATUS\_F1/0 pin after synchronization with the AXI clock (PCI\_ACLK) of the PCIe. Therefore, the register value is not reflected in the CFG\_PMCSR\_PME\_STATUS\_F1/0 pin while the AXI clock of the PCIe is stopped. It is reflected in the CFG\_PMCSR\_PME\_STATUS\_F1/0 pin after operation of the AXI clock of the PCIe.

49.3.2.28 PCI PME Status Clearing Confirmation Register (PCI\_PME\_STS\_CLR)

This register is for monitoring the ME\_STATUS clearing flag confirmation pins (CFG\_PMCSR\_PME\_STATUS\_WRITECLEAR\_F0/1) supplied from the PCIe.

Writing to this register has no effect.

Access Size: 32 bits  
Address(es): <SYS\_S0\_base> + 008Ch  
Initial Value: 0000\_00xxh (The initial value of bit 0 and bit 4 depends on the PME\_STATUS clearing flag.)

Table 49.3-35 PCI\_PME\_STS\_CLR Register Contents

| Bit Position | Bit Name | Description                             |
|--------------|----------|-----------------------------------------|
| 31 to 5      | Reserved | These bits are always read as 0b.       |
| 4            | F1       | PME_STATUS clearing flag for function 1 |
| 3 to 1       | Reserved | These bits are always read as 0b.       |
| 0            | F0       | PME_STATUS clearing flag for function 0 |

49.3.2.29 PCI Device Type Setting Register (PCI\_MODE)

This register controls the device type setting pin (MODE\_PORT) for output to the PCIe.

CAUTION

Since this register is for determining the operating mode of the PCIe, changing the setting during PCIe operation is prohibited.

Be sure to make the setting during the PCIe reset period.

| Bit Position | Bit Name | Description                                                     |
|--------------|----------|-----------------------------------------------------------------|
| 31 to 1      | Reserved | These bits are always read as 0b.                               |
| 0            | EN_B     | Macro off mode setting<br>0b: Normal operation<br>1b: Macro off |

CAUTION

The macro off setting of the PCIe unit can also be made from a register of the PCIe.  
When using the setting from a register of the PCIe, fix the value to 0b.

49.3.2.31 PCI Target Lane Setting Register (PCI\_LANE\_SEL)

This register controls the output target lane setting pin (PCI\_LANE\_SEL). The value of the SEL bit is notified to the PCIe via the PCI\_LANE\_SEL pin.

Access Size: 32 bits  
Address(es): <SYS\_S0\_base> + 00A0h  
Initial Value: 0000\_0000h

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |    |

### 49.3.2.32 MD[7:0] Port Monitor Register (SYS\_MD\_MON)

This register a read-only register that monitors the MD7 to MD0 pins. Writing to this register has no effect.

The initial value is determined by the state of the MD7 to MD0 pins.

**Access Size:** 32 bits

**Address(es):** <SYS\_S0\_base> + 0100h

**Initial Value:** 0000\_00xxh

|               |    |    |    |    |    |    |    |    |     |     |     |     |     |     |     |     |

| Bit Position | Bit Name | Description                                                                                                                                                                       |
|--------------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 9      | —        | Reserved. These bits are read as 0b.                                                                                                                                              |
| 8            | —        | Reserved. When read, the value read is undefined. The write value should always be 0b.                                                                                            |
| 7 to 1       | —        | Reserved. These bits are read as 0b.                                                                                                                                              |
| 0            | EN       | Setting whether RAMA ECC is enabled or disabled.<br>0b: ECC is disabled.<br>1b: ECC is enabled.<br>The value of this bit is notified to VECEN pin of the RAMA via RAMA_VECEN pin. |

49.3.2.35 RAMA ECC Code Region Initialization Control Register (SYS\_RAM\_INIT)

This register initializes the RAMA ECC code region.

Access Size: 32 bits  
Address(es): <SYS\_S0\_base> + 0114h  
Initial Value: 0000\_0000h

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |      |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------|
| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16   |

| Bit Position | Bit Name | Description                                                                                                                                                                                                             |
|--------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 1      | —        | Reserved. These bits are read as 0b.                                                                                                                                                                                    |
| 0            | INIT     | <p>RAMA ECC code region initialization control</p> <p>0b: Initialization is disabled.</p> <p>1b: Initialization is enabled.</p> <p>The value of this bit is notified to RAM_INIT pin of the RAMA via RAMA_INIT pin.</p> |

49.3.2.36 RAMA ECC Code Region Initialization End Flag Register (SYS\_RAM\_INIT\_END)

This register is a read-only register that indicates the end of initialization of the RAMA ECC code region. Writing to this register has no effect.

The initial value of the LSB one bit is determined by the state of the RAMA ECC code region initialization end flag.

|                |    |                       |    |    |    |    |    |    |    |    |    |    |    |    |    |     |

### 49.3.2.37 WDT Counter Stop Control Register (SYS\_WDT\_CNTSTOP)

This register controls stopping of the WDT counter.

**Access Size:** 32 bits

**Address(es):** <SYS\_S0\_base> + 0130h

**Initial Value:** 0000\_0000h

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |     |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----|-----|
| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17  | 16  |
|               | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —   | —   |
| Initial Value | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0   | 0   |

**Note:** Controlling stopping of the WDT is also possible from the CST.

### 49.3.2.38 CST Trigger Signal Monitor Register for WDT (SYS\_CST\_HLTDBG\_MON)

This register is a read-only register for monitoring the WDT trigger pin (CST\_HLTDBG[2:0]) input from the CST.

Writing to this register has no effect.

**Access Size:** 32 bits

**Address(es):** <SYS\_S0\_base> + 0134h

**Initial Value:** 0000\_000xh

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |      |      |      |

49.3.2.39 General-Purpose 32Bit Read/Write Register m (SYS\_GEN\_REGm) (m = 0 , 1)

This register is a general-purpose 32-bit read/write register.

Access Size: 32 bits  
Address(es): <SYS\_S0\_base> + 0200h (m = 0)  
<SYS\_S0\_base> + 0204h (m = 1)  
Initial Value: 0000\_0000h

Table 49.3-46 SYS\_GEN\_REGm Register Contents

| Bit Position | Bit Name  | Description                                                      |
|--------------|-----------|------------------------------------------------------------------|
| 31 to 0      | BIT[31:0] | A readable/writable register.<br>There are no special functions. |

49.3.2.40 ISP Support Package Control Register (SYS\_ISPPKG\_CNT\_REG)

This register is used to specify the HDMI PHY output resolution from the Linux OS to the ISP support package as a software processing instruction.

Access Size: 32 bits  
Address(es): <SYS\_S0\_base> + 0208h  
Initial Value: 0000\_0000h

Table 49.3-47 SYS\_ISPPKG\_CNT\_REG Register Contents

| Bit Position | Bit Name   | Description                                                               |
|--------------|------------|---------------------------------------------------------------------------|
| 31, 30       | BIT[31:30] | For more information, contact a Renesas Electronics sales representative. |

## 49.4 Functional Description

This section describes the functions of the SYS unit.

The prefix (SYS\_) of the register names is omitted in this and subsequent sections.

### 49.4.1 Bank Address Switching

The SYS has a bank switching register to extend the two higher-order bits of the addresses of the following IP modules which have only 32-bit (4-GB) address spaces. It makes 4 or more Gbytes of the address space accessible by switching the bank address.

Target unit 1: DRP-AI, eMMC, SDIO/1, ETHER, PCIe, USB, GRP, VCD

Target unit 2: DMAC

The specific functions are as follows.

- Target unit 1

Two bits for switching the bank address from the SYS are output to the ICB (common to the AR and AW channels).

- Target unit 2

Two bits for switching the bank address from the SYS are output to the DMAC (individually for the source, destination, and descriptor per DMAC number and channel of the DMAC).

The following restrictions apply to bank address switching.

- (1) When changing the bank address, only do so after all transactions by the target master have been completed.

*Note:* For the DMAC, changing the extended address for the corresponding DMAC number and channel is possible if the corresponding DMAC number and channel are not operating.

- (2) When starting a transaction by the target master following bank address switching, only do so after reading the bank address switching register to check its setting.
- (3) Access which spans across 32-bit address boundaries is prohibited.
- (4) Setting 11b and 10b is prohibited.

**Table 49.4-1** shows the correspondence between the bank addresses and the accessible address spaces.

Table 49.4-1 Correspondence between the Bank Addresses and the Accessible Address Spaces

| Bank Address[1:0] | Address Space      |
|-------------------|--------------------|
| 11b               | Setting prohibited |
| 10b               | Setting prohibited |
| 01b               | 01_FFFF_FFFFh      |
|                   | :                  |
|                   | 01_0000_0000h      |
| 00b               | 00_FFFF_FFFFh      |
|                   | :                  |
|                   | 00_0000_0000h      |

## 49.4.2 I/F Pins for ICB

### 49.4.2.1 ETH AxCACHE[1]

The SYS has a register to output the ARCACHE[1] and AWCACHE[1] signals in place of the ETHER and is able to control cacheable access by the ETHER.

The following restrictions apply to changing the settings of the cacheable bits.

- ARCACHE[1]:  
Changing the setting of the cacheable bit is only possible when all read transactions by the AXI master of ETHER have been completed.
- AWCACHE[1]:  
Changing the setting of the cacheable bit is only possible when all write transactions by the AXI master of ETHER have been completed.
- When starting a read transaction by the AXI master of ETHER following switching of ARCACHE[1], only do so after reading the ETH AxCACHE[1] (C bit) control register to check its setting.
- When starting a write transaction by the AXI master of ETHER following switching of AWCACHE[1], only do so after reading the ETH AxCACHE[1] (C bit) control register to check its setting.

### 49.4.2.2 Observability

The SYS has a register to output the ICB observability (OBS) counting stop control signal and is able to control stopping and operation of the OBS counter for the ICB.

### 49.4.3 PCIe-I/F Control

The SYS has the registers listed below.

These registers are used to monitor the pins supplied from the PCIe and control the pins for output to the PCIe.

#### Monitor registers

- PCI\_FLR\_REQ register
- PCI\_TURN\_OFF\_EVENT register
- PCI\_D3\_EVENT register
- PCI\_PME\_STS\_CLR register

#### Control registers

- PCI\_FLR\_RST register
- PCI\_INTX\_EP register
- PCI\_EXTMSI\_VAL register
- PCI\_EXTMSI\_SET0 register
- PCI\_EXTMSI\_SET1 register
- PCI\_EXTMSI\_SET2 register
- PCI\_EXTMSI\_SET3 register
- PCI\_EXTMSI\_SET4 register
- PCI\_ALLOW\_ENTER\_L1 register
- PCI\_PME\_TIM register
- PCI\_TURN\_OFF\_EVENT\_ACK register
- PCI\_D3\_EVENT\_ACK register
- PCI\_PME\_STS register
- PCI\_MODE register
- PCI\_MODE\_EN\_B register

### 49.4.4 RAMA Initialization Function

Register control by the SYS is required at the time of RAMA initialization.

For details of the functions, refer to the section of RAMA.

#### 49.4.5 Monitoring of MD0 to MD7 Pins

The SYS has functionality to monitor the values of the MD0 to MD7 pins by using the MD\_MON register (offset: 100h).

#### 49.4.6 LSI Version Register

The SYS includes a register to check the version number of this LSI chip.

#### 49.4.7 General-purpose 32-Bit Readable/Writable Registers

The SYS includes four general-purpose registers which are readable and writable in 32 bits. These registers have no special function for use in debugging, etc.

#### 49.4.8 WDT Counter Stop Control

The SYS outputs WDT counter STOP signal WDT\_CNTSTOP[1:0]. Signal WDT\_CNTSTOP[1:0] is logical OR of the values of the CST\_HLTDBG[1:0] input pin from the CST and the WDT\_CNTSTOP register of the SYS (offset: 130h).

0b: Counting by the WDT is possible.

1b: Stops counting by the WDT.

This function is used to stop the WDT counter so that WDT reset is not performed during a break in device debugging using the ICE.

Stop the counter upon a break and operate the counter in the RUN state.

**Figure 49.4-1** shows the WDT\_CNTSTOP[1:0] output signal generation circuit.

Figure 49.4-1 WDT\_CNTSTOP[1:0] Output Signal Generation Circuit

#### **49.4.9 Reading of the Temperature Sensor Reference Value**

The SYS has functionality for reading the reference value of the temperature sensor.

For details of the functions of the temperature sensor, see the section of Temperature Sensor (TSU).

## 49.5 Operating Procedure

### 49.5.1 Procedure for Writing to the Bank Address Switching Register

The 16 higher-order bits of the bank address switching register are write enable and the 16 lower-order bits are normal data registers, so changing only the value of the specified bits is possible without read-modify-write operation.

When changing the value, write 1 to the bit plus 16 of the bit to be changed.

*<Example>*

To set bit[0] to 1b, write 0001\_0001h. To set it to 0b, write 0001\_0000h. The value of bit[15:0] is not changed when 0000\_xxxxh is written

When read, the 16 higher-order bits are always read as 0b.

### 49.5.2 Procedure of Writing to the I/F Pin Control Registers for ICB

The procedure for writing to the bank address switching register also applies to the procedure for writing to the registers listed below.

- ETH\_CACHE\_C\_CNT register (offset: 220h)
- ICB\_OBS\_SUSP register (offset: 230h)

For details, see **Section 49.5.1, Procedure for Writing to the Bank Address Switching Register.**

### 49.5.3 Procedure for PCIe-I/F Control

For the operating procedure, refer to the section of PCIe.

### 49.5.4 RAMA Initialization Procedure

See **Section 49.4.4, RAMA Initialization Function.**

### 49.5.5 WDT Counter Stop Control Procedure

See **Section 49.4.8, WDT Counter Stop Control.**

## 49.6 Usage Notes

### 49.6.1 Bank Address Switching

- When changing the bank address, only do so after all transactions by the target master have been completed.  
For the DMAC, changing the extended address for the corresponding DMAC number and channel is possible if the corresponding DMAC number and channel are not operating.
- When starting a transaction by the target master following bank address switching, only do so after checking that the expected value has been set in the target register after writing to it.
- Access which spans across 32-bit address boundaries is prohibited.

### 49.6.2 PCIe Register Control

- Changing the setting for operation as an endpoint or root complex in the PCI device type setting register (SYS: PCI\_MODE) is prohibited while the PCI is operating. Be sure to make the setting while operation of the PCI is stopped.
- The PCI macro off mode setting can also be made by using a register in the PCI. When setting the PCI macro off mode with a register in the PCI, fix the EN\_B bit of the PCI macro off mode setting register in the SYS (SYS: PCI\_MODE\_EN\_B) to 0b.
- For the following registers, be sure to supply the PCI\_ACLK clock before setting values.
  - PCI FLR execution instruction reset register (SYS: PCI\_FLR\_RST)
  - PCI MSI issuing register (SYS: PCI\_EXTMSI\_VAL)
  - PCI issued MSI setting register 0 (SYS: PCI\_EXTMSI\_SET0)
  - PCI issued MSI setting register 1 (SYS: PCI\_EXTMSI\_SET1)
  - PCI issued MSI setting register 2 (SYS: PCI\_EXTMSI\_SET2)
  - PCI issued MSI setting register 3 (SYS: PCI\_EXTMSI\_SET3)
  - PCI issued MSI setting register 4 (SYS: PCI\_EXTMSI\_SET4)
- Writing to the following registers twice or more is prohibited while PCI\_ACLK is stopped (read the register value before writing a value again).
  - PCI issued MSI setting register 0 (SYS: PCI\_EXTMSI\_SET0)
  - PCI issued MSI setting register 1 (SYS: PCI\_EXTMSI\_SET1)
  - PCI issued MSI setting register 2 (SYS: PCI\_EXTMSI\_SET2)
  - PCI issued MSI setting register 3 (SYS: PCI\_EXTMSI\_SET3)
  - PCI issued MSI setting register 4 (SYS: PCI\_EXTMSI\_SET4)

## Section 50 Debugger (CST)

For connecting the debugger, contact a Renesas Electronics sales representative.

## Section 51 Electrical Characteristics

This section describes the electrical characteristics of this LSI.

### 51.1 Absolute Maximum Ratings

Permanent damage to the LSI may result if absolute maximum ratings are exceeded.

Table 51.1-1 Absolute Maximum Ratings (1/3)

| Item                                                      | Symbol                 | Min. | Max. | Unit |

51.3 Power-On/Off Procedures

51.3.1 Power-On Sequence (RTC/PWC)

Figure 51.3-1 Power-On Sequence (RTC/PWC)

### 51.3.2 Power-On/Off Sequence (other than for RTC/PWC)

#### 51.3.2.1 Power-On Sequence (other than for RTC/PWC)

Figure 51.3-2 Power-On Sequence (other than for RTC/PWC)

Table 51.3-1, Table 51.3-2, and Table 51.3-3 show the correspondence between the power supplies and the power-on (off) timings.

Table 51.3-1 Various Power Supplies and Power On/Off Timings

| Power Voltage | Power Supply Name                                       | Timing   |
|---------------|---------------------------------------------------------|----------|
| 0.8 V         | VDD08                                                   | Timing.1 |
| 1.1 V         | LPVDDQ                                                  |          |
| 1.8 V         | VDD18, LPVAA                                            |          |
| 0.8 V         | DSMSVDD0P8, PCVDD08, HDAVDD08, OTVDD08, LVRXAVDD        | Timing.2 |
| 1.8 V         | DSMSVDD18, PCVDD18, HDAVDD18, OTVDD18, LVRXAVCC, USVDDH | Timing.3 |
| 3.3 V         | VDD33, USVD330, USVPH                                   | Timing.4 |
| 1.2 V         | DSMVDD12                                                |          |
| 0.8 V         | USDVDD, USVP, USVPTX, LPVDD*1                           | Timing.5 |

Note 1. When not controlled by the System FW, the power is on (off) at Timing.5.  
 When controlled by the System FW, connect the 0.8-V power supply to the LPVDD pin of this LSI via the power switch. In addition, connect the PWMEMSWIENA pin of this LSI to an enable pin of this power switch.

Table 51.3-2 Various Power Supplies and Power On/Off Timings (PLL, TSU, ADC, etc.)

| Power Voltage | Power Supply Name                                                                   | Timing               |
|---------------|-------------------------------------------------------------------------------------|----------------------|
| 0.8 V         | PLDVDD08n (n = 1, 2, 3, 4, 6, 7), TSnDVDD08A (n = 0, 1)                             | Timing.1 or Timing.2 |
| 1.8 V         | PLVDDn (n = 1, 2, 3, 4, 6, 7), TSnAVDD18 (n = 0, 1), ADnAVCCA (n = 0, 1), PREDVDD33 | Timing.1 or Timing.3 |

Table 51.3-3 Various Power Supplies and Power On/Off Timings (1.8-V/3.3-V Switching I/O)

| I/O Voltage           | Power Supply Name         | Case | Timing   |
|-----------------------|---------------------------|------|----------|
| Used as the 1.8-V I/O | Pre-driver power supply*1 | 1    | Timing.1 |
|                       | I/O power supply*2        |      |          |
|                       | Pre-driver power supply*1 | 2    | Timing.1 |
|                       | I/O power supply*2        |      | Timing.3 |
|                       | Pre-driver power supply*1 | 3    | Timing.3 |
|                       | I/O power supply*2        |      |          |
| Used as the 3.3-V IO  | Pre-driver power supply*1 | 4    | Timing.1 |
|                       | I/O power supply*2        |      | Timing.4 |
|                       | Pre-driver power supply*1 | 5    | Timing.3 |
|                       | I/O power supply*2        |      | Timing.4 |

Note 1. NAPREDVDD, PAPREDVDD, PBPREDVDD, PCPREDVDD, SD0PREDVDD, SD1FVDD, IM0PREDVDD, IM1PREDVDD, GEPREDVDD

Note 2. NAMODVDD, PAMODVDD, PBMODVDD, PCMODVDD, SD0MODVDD, SD1FMODVDD, IM0MODVDD, IM1MODVDD, GEMODVDD

The following restrictions apply to the order of turning on the pre-driver power supply and the I/O power supply for the power supply of the 1.8-V/3.3-V switching I/O.

- When used as the 1.8-V I/O, “the pre-driver power supply and the I/O power supply are turned on at the same time” or “the pre-driver power supply is turned on first and then the I/O power supply”.
- When used as the 3.3-V I/O, “the pre-driver power supply is turned on first and then the I/O power supply”.

When used as the 1.8-V I/O, the pre-driver power supply and the I/O power supply must be turned on or off in case 1, 2, or 3. When used as the 3.3-V I/O, they must be turned on or off in case 4 or 5.

### 51.3.2.2 Power-Off Sequence (other than for RTC/PWC)

**Note:** The power off time difference must be minimized.

**Note 1.** The power supply in the case of Timing.2 (0.8 V) must be turned off no less than 0 ns after the power supply in the case of Timing.3 (1.8 V) is turned off and the power supply in the case of Timing.3 (1.8 V) must be turned off no less than 0 ns after the power supply in the case of Timing.4 (1.2 V) is turned off.

(Continuation of the previous page)

- Note 2. The power supply in the case of Timing.3 (1.8 V) must be turned off no less than 0 ns after the power supply in the case of Timing.4 (3.3 V) is turned off.
- Note 3. The 0.8-V power supply and the 1.8-V power supply are indicated in the case of Timing.1 and Timing.3, respectively.  
No restrictions apply to the order of turning off the 0.8-V power supply and the 1.8-V power supply.
- Note 4. This is used as the 3.3-V I/O, and the pre-driver power supply and the I/O power supply are indicated in the case of Timing.1 and Timing.4, respectively.  
The pre-driver power supply must be turned off no less than 0 ns after the I/O power supply is turned off.  
When used as the 1.8-V I/O, no restrictions apply to the order of turning on the pre-driver power supply and the I/O power supply.

| USB PHY 3.3-V power supply current                                                                                                  | $I_{DDUS33}$    | 57   | mA   | Total of $USV_{D330}$ , $USV_{PH}$                                                                              |

Note 1. Reference value for the RTC core power supply current (at normal temperature at 0.8 V): 35  $\mu$ A

Note 2. Reference value for the RTC I/O, 1.5-V OSC power supply current (at normal temperature at 1.5 V): 10  $\mu$ A

Note 3. In normal operation (when the power supplies other than for the RTC power domain are turned on), current flows to the PWISO pin via a pull-up resistor, so this amount of current must be taken into account when the current drawn is estimated.  
[Example] When the pull-up resistance is 10 k $\Omega$ , 1.5 V/10 k $\Omega$  = 150  $\mu$ A

### 51.4.2 Standard I/O Characteristics

For the I/O groups, refer to the multiplexed pin group numbers in the list of external pins.

Table 51.4-2 DC Characteristics

$V_{DD} = 1.35 \text{ V to } 1.65 \text{ V}$  (1.5-V I/O group),  $V_{DD} = 1.65 \text{ V to } 1.95 \text{ V}$  (1.8-V I/O groups 1, 2, 3, and 4),  $V_{DD} = 1.65 \text{ V to } 3.60 \text{ V}$  (3.3/1.8-V switching I/O groups 1 and 2),  $V_{DD} = 3.00 \text{ V to } 3.60 \text{ V}$  (3.3-V I/O group)

| Item                                                               |                                   | Symbol     | Min.                 | Typ. | Max.                | Unit          | Condition                                                   |

## 51.6 Various Analog Characteristics

### 51.6.1 MIPI CSI-2 PHY Characteristics

The MIPI CSI-2 Rx D-PHY of this LSI is equivalent to the MIPI CSI-2 Ver.1.2/D-PHY Ver.1.2. For details, refer to the MIPI specification.

### 51.6.2 HDMI Tx PHY Characteristics

The HDMI Tx PHY of this LSI is compliant with the following HDMI 1.4a standard:

Version 1.4a of *the High-Definition Multimedia Interface Specification*, released on March 4, 2010

### 51.6.3 LPDDR4 PHY Characteristics

The LPDDR4 PHY of this LSI is compliant with the JEDEC 209-4A standard.

### 51.6.4 USB PHY Characteristics

The USB PHY of this LSI is compliant with the following USB 3.1 GEN1 standard:

*Universal Serial Bus 3.1 Specification*

### 51.6.5 PCI Express PHY Characteristics

The PCI Express PHY of this LSI is compliant with the following PCIe standard:

Revision 4.0 of *the PCI Express® Base Specification* for Gen1/Gen 2

### 51.6.6 ADC Characteristics

Table 51.6-1 DC Characteristics

| Item                       | Symbol | Min. | Typ. | Max. | Unit | Test Condition            |
|----------------------------|--------|------|------|------|------|---------------------------|
| Resolution                 | —      | —    | 12   | —    | Bit  |                           |
| Differential non-linearity | DNL    | —    | ±1.0 | ±3.0 | LSB  | FAIN = 100 kHz, Ramp wave |
| Integral non-linearity     | INL    | —    | ±2.0 | ±6.0 | LSB  |                           |
| Top offset voltage         | EOT    | —    | ±10  | ±20  | LSB  |                           |
| Bottom offset voltage      | EOB    | —    | ±10  | ±20  | LSB  |                           |

Table 51.6-2 AC Characteristics

51.7 Oscillation Circuits for Connecting Crystal Resonators (OSC)

This LSI chip includes two oscillation circuits (OSC) for connection to crystal resonators, specifically a 48-MHz crystal resonator for the system clock and a 32.768-kHz crystal resonator for the real-time clock. **Table 51.7-1** lists the pins for connecting the crystal resonators and the clock frequencies. **Figure 51.7-1** shows an example of the connections with crystal resonators.

Table 51.7-1 Pins for Connecting Crystal Resonators and Clock Frequency

| External Pin Name       | I/O    | Clock Frequency                                                                      |
|-------------------------|--------|--------------------------------------------------------------------------------------|
| For the system clock    |        |                                                                                      |
| XIN                     | Input  | 48 MHz (frequency deviation: ±50 ppm, frequency temperature characteristic: ±30 ppm) |
| XOUT                    | Output | 48 MHz                                                                               |
| For the real-time clock |        |                                                                                      |
| RTXIN                   | Input  | 32.768 kHz (frequency deviation: ±20 ppm)                                            |
| RTXOUT                  | Output | 32.768 kHz                                                                           |

Figure 51.7-1 Example of Connections with Crystal Resonators

Place the crystal resonators and the capacitors  $C_{L1}$  and  $C_{L2}$  as close as possible to the pins to connect crystal resonators. To avoid interference and to ensure correct oscillation, the grounding points of the capacitors appended to the crystal resonators should be shared, and no wiring patterns should be placed near these components.

The characteristics of the crystal resonators are closely related to the design of the user board. Therefore, the user should sufficiently evaluate them with reference to the example of connection of crystal resonators in **Figure 51.7-1**.

The circuit rating of a crystal resonator depends on the crystal resonator and the stray capacitance of the mounting circuit. Therefore, contact the manufacturer of the crystal resonator before deciding upon the circuit rating. The user should thoroughly evaluate and then set the parameters (resistor and capacitor values).

**Table 51.7-2** is a list of recommended values for the crystal resonators.

Table 51.7-2 Recommended Model Values for the Crystal Resonators

| Clock Frequency | Model Values for the Crystal Resonators |                           |                           |                  |
|-----------------|-----------------------------------------|---------------------------|---------------------------|------------------|
|                 | Max. ESR* <sup>1</sup>                  | Max. $C_L$ * <sup>2</sup> | Max. $C_0$ * <sup>3</sup> | Max. Drive Level |
| 32.768 kHz      | 70 k $\Omega$                           | 12.5 pF                   | 1.4 pF                    | 1 $\mu$ W        |
| 48 MHz          | 50 $\Omega$                             | 10 pF                     | 7 pF                      | 100 $\mu$ W      |

Note 1. ESR means the equivalent series resistor of the crystal resonator.

Note 2.  $C_L$  is the load capacitance of the crystal resonator.

Note 3.  $C_0$  is the parallel capacitance of the crystal resonator.
