User's Manual: Hardware

VisionAI ASSP  
RZ Family RZ/V Series  
The ARM logo, consisting of the word "arm" in a lowercase, blue, sans-serif font.

All information contained in these materials, including products and product specifications, represents information on the product at the time of publication and is subject to change by Renesas Electronics Corp. without notice. Please review the latest information published by Renesas Electronics Corp. through various means, including the Renesas Electronics Corp. website (<http://www.renesas.com>).

# Notice

1. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation or any other use of the circuits, software, and information in the design of your product or system. Renesas Electronics disclaims any and all liability for any losses and damages incurred by you or third parties arising from the use of these circuits, software, or information.
2. Renesas Electronics hereby expressly disclaims any warranties against and liability for infringement or any other claims involving patents, copyrights, or other intellectual property rights of third parties, by or arising from the use of Renesas Electronics products or technical information described in this document, including but not limited to, the product data, drawings, charts, programs, algorithms, and application examples.
3. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.
4. You shall be responsible for determining what licenses are required from any third parties, and obtaining such licenses for the lawful import, export, manufacture, sales, utilization, distribution or other disposal of any products incorporating Renesas Electronics products, if required.
5. You shall not alter, modify, copy, or reverse engineer any Renesas Electronics product, whether in whole or in part. Renesas Electronics disclaims any and all liability for any losses or damages incurred by you or third parties arising from such alteration, modification, copying or reverse engineering.
6. Renesas Electronics products are classified according to the following two quality grades: "Standard" and "High Quality". The intended applications for each Renesas Electronics product depends on the product's quality grade, as indicated below.

"Standard": Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; industrial robots; etc.

"High Quality": Transportation equipment (automobiles, trains, ships, etc.); traffic control (traffic lights); large-scale communication equipment; key financial terminal systems; safety control equipment; etc.

Unless expressly designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not intended or authorized for use in products or systems that may pose a direct threat to human life or bodily injury (artificial life support devices or systems; surgical implantations; etc.), or may cause serious property damage (space system; undersea repeaters; nuclear power control systems; aircraft control systems; key plant systems; military equipment; etc.). Renesas Electronics disclaims any and all liability for any damages or losses incurred by you or any third parties arising from the use of any Renesas Electronics product that is inconsistent with any Renesas Electronics data sheet, user's manual or other Renesas Electronics document.

7. No semiconductor product is absolutely secure. Notwithstanding any security measures or features that may be implemented in Renesas Electronics hardware or software products, Renesas Electronics shall have absolutely no liability arising out of any vulnerability or security breach, including but not limited to any unauthorized access to or use of a Renesas Electronics product or a system that uses a Renesas Electronics product. RENESAS ELECTRONICS DOES NOT WARRANT OR GUARANTEE THAT RENESAS ELECTRONICS PRODUCTS, OR ANY SYSTEMS CREATED USING RENESAS ELECTRONICS PRODUCTS WILL BE INVULNERABLE OR FREE FROM CORRUPTION, ATTACK, VIRUSES, INTERFERENCE, HACKING, DATA LOSS OR THEFT, OR OTHER SECURITY INTRUSION ("Vulnerability Issues"). RENESAS ELECTRONICS DISCLAIMS ANY AND ALL RESPONSIBILITY OR LIABILITY ARISING FROM OR RELATED TO ANY VULNERABILITY ISSUES. FURTHERMORE, TO THE EXTENT PERMITTED BY APPLICABLE LAW, RENESAS ELECTRONICS DISCLAIMS ANY AND ALL WARRANTIES, EXPRESS OR IMPLIED, WITH RESPECT TO THIS DOCUMENT AND ANY RELATED OR ACCOMPANYING SOFTWARE OR HARDWARE, INCLUDING BUT NOT LIMITED TO THE IMPLIED WARRANTIES OF MERCHANTABILITY, OR FITNESS FOR A PARTICULAR PURPOSE.
8. When using Renesas Electronics products, refer to the latest product information (data sheets, user's manuals, application notes, "General Notes for Handling and Using Semiconductor Devices" in the reliability handbook, etc.), and ensure that usage conditions are within the ranges specified by Renesas Electronics with respect to maximum ratings, operating power supply voltage range, heat dissipation characteristics, installation, etc. Renesas Electronics disclaims any and all liability for any malfunctions, failure or accident arising out of the use of Renesas Electronics products outside of such specified ranges.
9. Although Renesas Electronics endeavors to improve the quality and reliability of Renesas Electronics products, semiconductor products have specific characteristics, such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Unless designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not subject to radiation resistance design. You are responsible for implementing safety measures to guard against the possibility of bodily injury, injury or damage caused by fire, and/or danger to the public in the event of a failure or malfunction of Renesas Electronics products, such as safety design for hardware and software, including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult and impractical, you are responsible for evaluating the safety of the final products or systems manufactured by you.
10. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. You are responsible for carefully and sufficiently investigating applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive, and using Renesas Electronics products in compliance with all these applicable laws and regulations. Renesas Electronics disclaims any and all liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.
11. Renesas Electronics products and technologies shall not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations. You shall comply with any applicable export control laws and regulations promulgated and administered by the governments of any countries asserting jurisdiction over the parties or transactions.
12. It is the responsibility of the buyer or distributor of Renesas Electronics products, or any other party who distributes, disposes of, or otherwise sells or transfers the product to a third party, to notify such third party in advance of the contents and conditions set forth in this document.
13. This document shall not be reprinted, reproduced or duplicated in any form, in whole or in part, without prior written consent of Renesas Electronics.
14. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products.

(Note1) "Renesas Electronics" as used in this document means Renesas Electronics Corporation and also includes its directly or indirectly controlled subsidiaries.

(Note2) "Renesas Electronics product(s)" means any product developed or manufactured by or for Renesas Electronics.

## Corporate Headquarters

TOYOSU FORESIA, 3-2-24 Toyosu,  
Koto-ku, Tokyo 135-0061, Japan

[www.renesas.com](http://www.renesas.com)

## Trademarks

Renesas and the Renesas logo are trademarks of Renesas Electronics Corporation. All trademarks and registered trademarks are the property of their respective owners.

## Contact information

For further information on a product, technology, the most up-to-date version of a document, or your nearest sales office, please visit:

[www.renesas.com/contact/](http://www.renesas.com/contact/)

## Trademarks (continued)

For the “Cortex” notation, it is used as follows;

— Arm® Cortex®-A53

Note that in each section of the Manual, this may be noted as Cortex-A53 respectively.

Examples of trademark or registered trademark used in the document of RZ/V2M;

AMBA®: AMBA is a registered trademark of Arm Limited.

CoreLink™: CoreLink is a trademark of Arm Limited.

CoreSight™: CoreSight is a trademark of Arm Limited.

Neon™: Neon is a trademark of Arm Limited.

eMMC™: eMMC is a trademark of MultiMediaCard Association.

BENAND™: BENAND is a trademark of Toshiba Corporation.

Magic Packet™: Magic Packet is a trademark of Advanced Micro Devices, INC.

PCIe®: PCIe is a registered trademark of PCI-SIG, Inc.

PCI Express®: PCI Express is a registered trademark of PCI-SIG, Inc.

HDCP™: HDCP is a trademark of Digital Content Protection LLC.

HDMI®: HDMI is a registered trademark of HDMI Licensing, LLC.

MIPI®: MIPI is a registered trademark of MIPI Alliance, Inc.

Note that in each section of the Manual, trademark notation of ® and TM may be omitted.

All other trademarks and registered trademarks are the property of their respective owners.

## Notes on the Use of Specific Technologies

1. You are required to obtain a license for the use of the technologies listed in the table below (hereinafter referred to as the "specific technology" or "specific technologies"), that are used in this LSI chip. You shall correctly obtain a license for the use of each specific technology that is in use or available for use and maintain the validity of all such licenses for as long as any of your products incorporating this LSI chip continue to be manufactured, sold, or in use. In addition, if you manufacture and supply products that incorporate this LSI chip for sale under the trademark of a third party (OEM supply), you are requested to notify such third parties that obtaining licenses for the use of the specific technologies will be required.

| Technology Name |
|-----------------|
| HDMI            |
| SD              |
| H.264           |
| H.265           |

2. Renesas Electronics do not grant any rights to you, and make no warranties of any kind, including but not limited to warranties of merchantability and compatibility with specific purposes and warranties of non-infringement of third party rights. In the event that you receive a claim from a third party due to your failure to correctly obtain a license to use a specific technology, you shall resolve the claim at your own responsibility and expense. Renesas Electronics shall not be liable for any damages, liabilities, or costs that may be incurred by you or any third party.

# General Precautions in the Handling of Microprocessing Unit and Microcontroller Unit Products

The following usage notes are applicable to all Microprocessing unit and Microcontroller unit products from Renesas. For detailed usage notes on the products covered by this document, refer to the relevant sections of the document as well as any technical updates that have been issued for the products.

## 1. Precaution against Electrostatic Discharge (ESD)

A strong electrical field, when exposed to a CMOS device, can cause destruction of the gate oxide and ultimately degrade the device operation. Steps must be taken to stop the generation of static electricity as much as possible, and quickly dissipate it when it occurs. Environmental control must be adequate. When it is dry, a humidifier should be used. This is recommended to avoid using insulators that can easily build up static electricity.

Semiconductor devices must be stored and transported in an anti-static container, static shielding bag or conductive material. All test and measurement tools including work benches and floors must be grounded. The operator must also be grounded using a wrist strap. Semiconductor devices must not be touched with bare hands. Similar precautions must be taken for printed circuit boards with mounted semiconductor devices.

## 2. Processing at power-on

The state of the product is undefined at the time when power is supplied. The states of internal circuits in the LSI are indeterminate and the states of register settings and pins are undefined at the time when power is supplied. In a finished product where the reset signal is applied to the external reset pin, the states of pins are not guaranteed from the time when power is supplied until the reset process is completed. In a similar way, the states of pins in a product that is reset by an on-chip power-on reset function are not guaranteed from the time when power is supplied until the power reaches the level at which resetting is specified.

## 3. Input of signal during power-off state

Do not input signals or an I/O pull-up power supply while the device is powered off. The current injection that results from input of such a signal or I/O pull-up power supply may cause malfunction and the abnormal current that passes in the device at this time may cause degradation of internal elements. Follow the guideline for input signal during power-off state as described in your product documentation.

## 4. Handling of unused pins

Handle unused pins in accordance with the directions given under handling of unused pins in the manual. The input pins of CMOS products are generally in the high-impedance state. In operation with an unused pin in the open-circuit state, extra electromagnetic noise is induced in the vicinity of the LSI, an associated shoot-through current flows internally, and malfunctions occur due to the false recognition of the pin state as an input signal become possible.

## 5. Clock signals

After applying a reset, only release the reset line after the operating clock signal becomes stable. When switching the clock signal during program execution, wait until the target clock signal is stabilized. When the clock signal is generated with an external resonator or from an external oscillator during a reset, ensure that the reset line is only released after full stabilization of the clock signal. Additionally, when switching to a clock signal produced with an external resonator or by an external oscillator while program execution is in progress, wait until the target clock signal is stable.

## 6. Voltage application waveform at input pin

Waveform distortion due to input noise or a reflected wave may cause malfunction. If the input of the CMOS device stays in the area between  $V_{IL}$  (Max.) and  $V_{IH}$  (Min.) due to noise, for example, the device may malfunction. Take care to prevent chattering noise from entering the device when the input level is fixed, and also in the transition period when the input level passes through the area between  $V_{IL}$  (Max.) and  $V_{IH}$  (Min.).

## 7. Prohibition of access to reserved addresses

Access to reserved addresses is prohibited. The reserved addresses are provided for possible future expansion of functions. Do not access these addresses as the correct operation of the LSI is not guaranteed.

## 8. Differences between products

Before changing from one product to another, for example to a product with a different part number, confirm that the change will not lead to problems. The characteristics of a microprocessing unit or microcontroller unit products in the same group but having a different part number might differ in terms of internal memory capacity, layout pattern, and other factors, which can affect the ranges of electrical characteristics, such as characteristic values, operating margins, immunity to noise, and amount of radiated noise. When changing to a product with a different part number, implement a system-evaluation test for the given product.

# How to Use This Manual

## 1. Objective and Target Users

This manual was written to explain the hardware functions and electrical characteristics of this LSI to the target users, i.e. those who will be using this LSI chip in the design of application systems. Target users are expected to understand the fundamentals of electrical circuits, logic circuits, and microcomputers.

This manual is structured to cover the following items: an overview of the product, descriptions of the CPU, system control functions, and peripheral functions, electrical characteristics of the device, and usage notes.

---

When designing an application system that includes this LSI chip, take all points to note into account. Points to note are given in their contexts, at the final parts of each of the sections, and in the section giving usage notes.

---

---

The list of revisions is a summary of major points of revision or addition for this and earlier versions. It does not cover all revised items. For details on the revised points, see the actual locations in the manual.

---

---

This manual is a simplified version. Please contact a Renesas Electronics sales representative for the detailed version of the manual.

---

## 2. Description of Registers

Each register description includes a bit chart, illustrating the arrangement of bits, and a table of bits, describing the meanings of the bit settings. The standard format and notation for use with bit charts and tables are described below.

### [Bit Chart]

### [Table of Bits]

| Bit Position | Bit Name    | Description                                                                                                                                                                                                                                                              |
|--------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15, 14       | —           | Reserved<br>These bits are read as 0b. The write value should be always 0b.                                                                                                                                                                                              |
| 13 to 8      | PD_ON_TIM   | Set the power-on time for power domain unit.                                                                                                                                                                                                                             |
| 7            | —           | Reserved<br>These bits are read as 0b. The write value should be always 0b.                                                                                                                                                                                              |
| 6            | ON          | Writing to this register starts the process of turning on/off the power domain.<br>0b: Power off<br>1b: Power on                                                                                                                                                         |
| 5 to 3       | —           | Reserved<br>These bits are read as 0b. The write value should be always 0b.                                                                                                                                                                                              |
| 2 to 0       | PD_NUM[2:0] | Specify the power domain to be turned on/off.<br>000b: The power on/off process does not start.<br>001b: The processing target is PD_1.<br>010b: The processing target is PD_2.<br>100b: The processing target is PD_3.<br>Settings other than the above are prohibited. |

**Note:** The bit names and statements in the above figure and table are examples and have nothing to do with the main contents of this manual.

#### (1) Bit

Indicates the bit number or numbers.

In the case of a 64-bit register, the bits are arranged in order from 63 to 0.

In the case of a 32-bit register, the bits are arranged in order from 31 to 0.

#### (2) Bit name

Indicates the name of the bit or bit field.

When the number of bits must be clearly indicated for a bit field, appropriate notation is included (e.g., PD\_NUM[2:0]).

Certain kinds of bits, such as those of timer counters, are not assigned bit names. In such cases, the entry under “Bit Name” is blank (e.g., PD\_ON\_TIM).

A reserved bit is indicated by “—”. Make sure to use the specified values when writing to such bits or fields. Otherwise, the correct operation of this LSI chip is not guaranteed.

### (3) Initial value

Indicates the initial value of each bit.

- 0: The initial value is 0.
- 1: The initial value is 1.
- x/—: The initial value is undefined.

### (4) R/W

For each bit and bit field, this entry indicates whether the bit or field is readable, writable, or both, and whether writing to and reading from the bit or field are impossible.

The notation is as follows:

- RW: The bit or field is readable and writable.
- RW0: The bit or field is readable and writable with 0. Writing 1 is invalid.
- RW1: The bit or field is readable and writable with 1. Writing 0 is invalid.
- R0W: The bit or field is readable as 0 and writable.
- R1W: The bit or field is readable as 1 and writable.
- R: The bit or field is readable. Writing is invalid.
- R0W0: The bit or field is readable as 0 and writable with 1. Writing 1 is invalid.
- R0W1: The bit or field is readable as 0 and writable with 1. Writing 0 is invalid.
- R1W0: The bit or field is readable as 1 and writable as 0. Writing 1 is invalid.
- R1W1: The bit or field is readable as and writable as 1. Writing 0 is invalid.
- RCW0: The bit or field is readable and writable with 0. Reading the bit initializes it. Writing 1 is invalid.
- RCW1: The bit or field is readable and writable with 1. Reading the bit initializes it. Writing 0 is invalid.

### (5) Description

Describes the function of the bit or field and specifies the values for writing.

**Note:** Access to reserved addresses is prohibited.

**Do not access these addresses. In case of access, correct operation of this LSI chip is not guaranteed.**

## 3. Notation of Numbers and Symbols

Number notation: Binary numbers are given as XXXXb (or B'XXXX, b'XXXX), hexadecimal numbers are given as XXXXh (or H'XXXX, h'XXXX, 0xXXXX), and decimal numbers are given as XXXX.

| <b>Section 33</b> | <b>eMMC Host Interface (eMMC) .....</b>                 | <b>397</b> |
| 33.1              | Functional Overview .....                               | 397        |
| 33.2              | Block Diagram .....                                     | 397        |
| 33.3              | Pin Functions .....                                     | 398        |
| 33.4              | Address Map.....                                        | 398        |
| 33.5              | eMMC Interface .....                                    | 399        |
| 33.5.1            | Overview .....                                          | 399        |
| <b>Section 34</b> | <b>USB3.1 Gen1 Interface (USB) .....</b>                | <b>400</b> |
| 34.1              | Functional Overview .....                               | 400        |
| 34.2              | Connection Configuration .....                          | 401        |
| 34.3              | Pin Functions .....                                     | 402        |
| 34.4              | USB3.1 Gen1 Dual Role Device Controller (USB3DRD) ..... | 403        |
| 34.4.1            | Introduction .....                                      | 403        |
| 34.4.1.1          | Features.....                                           | 403        |
| 34.4.2            | Resets .....                                            | 405        |
| 34.4.2.1          | Internal Reset Inputs.....                              | 405        |
| 34.4.3            | Interrupts .....                                        | 406        |
| 34.4.3.1          | Interrupt Diagram .....                                 | 406        |
| 34.4.3.2          | Interrupt Sources .....                                 | 407        |
| 34.4.4            | Registers Specification .....                           | 409        |
| 34.4.4.1          | Register Overview.....                                  | 409        |
| 34.4.4.2          | Registers List .....                                    | 410        |

|          |                                                                   |     |
|----------|-------------------------------------------------------------------|-----|
| 34.4.4.3 | Register Initial Value .....                                      | 414 |
| 34.4.5   | Register Descriptions .....                                       | 415 |
| 34.4.5.1 | DRD Common Registers .....                                        | 415 |
| 34.4.5.2 | Battery Charging Registers .....                                  | 423 |
| 34.4.5.3 | Global Purpose Registers .....                                    | 426 |
| 34.4.6   | Description of Functions .....                                    | 430 |
| 34.4.6.1 | DRD Mode .....                                                    | 430 |
| 34.4.6.2 | Battery Charging Function .....                                   | 435 |
| 34.4.6.3 | Over Current Checking Flow .....                                  | 444 |
| 34.4.6.4 | Control of SuspendM Signal .....                                  | 446 |
| 34.5     | USB3.1 Gen1 Host Controller (USB3HOST) .....                      | 447 |
| 34.5.1   | Introduction .....                                                | 447 |
| 34.5.1.1 | Features .....                                                    | 447 |
| 34.5.2   | Interrupts .....                                                  | 449 |
| 34.5.2.1 | Interrupt Diagram .....                                           | 449 |
| 34.5.2.2 | Interrupt Sources .....                                           | 450 |
| 34.5.3   | Register Specification .....                                      | 451 |
| 34.5.3.1 | Register Overview .....                                           | 452 |
| 34.5.3.2 | Register List of Each Category .....                              | 456 |
| 34.5.4   | Register Descriptions .....                                       | 472 |
| 34.5.4.1 | Host Controller Capability Registers .....                        | 472 |
| 34.5.4.2 | Host Controller Operational Registers .....                       | 481 |
| 34.5.4.3 | Port Register Sets in Host Controller Operational Registers ..... | 492 |
| 34.5.4.4 | xHCI Extended Capabilities .....                                  | 506 |
| 34.5.4.5 | Host Controller Runtime Registers .....                           | 526 |
| 34.5.4.6 | Doorbell Registers .....                                          | 534 |
| 34.5.4.7 | Core Defined Registers .....                                      | 537 |
| 34.5.5   | Description of Functions .....                                    | 557 |
| 34.5.5.1 | Battery Charging .....                                            | 557 |
| 34.5.5.2 | Initialization Flow .....                                         | 559 |
| 34.5.5.3 | xHCD Initialization Flow .....                                    | 560 |
| 34.5.5.4 | Interrupt Flow .....                                              | 562 |
| 34.5.5.5 | xHCI Command .....                                                | 567 |
| 34.5.5.6 | Examples of Transactions' Flow .....                              | 568 |
| 34.5.5.7 | Functional Implementation Constraint .....                        | 570 |
| 34.6     | USB3.1 Gen1 Peripheral Controller (USB3PERI) .....                | 571 |
| 34.6.1   | Introduction .....                                                | 571 |
| 34.6.1.1 | Features .....                                                    | 571 |
| 34.6.1.2 | Block Diagram .....                                               | 572 |
| 34.6.2   | Register Map .....                                                | 573 |
| 34.6.2.1 | USB3PERI Address Space .....                                      | 573 |
| 34.6.2.2 | AXI Register .....                                                | 574 |
| 34.6.2.3 | EPC Register .....                                                | 577 |
| 34.6.2.4 | SSIF Register (a part of EPC Register) .....                      | 587 |
| 34.6.3   | Register Descriptions .....                                       | 589 |
| 34.6.3.1 | AXI Register .....                                                | 589 |
| 34.6.3.2 | Physical Region Descriptor (PRD) Table .....                      | 612 |
| 34.6.3.3 | EPC Register .....                                                | 615 |
| 34.6.3.4 | SSIF Register .....                                               | 672 |
| 34.6.4   | Details of Functions .....                                        | 681 |

|           |                                       |     |
|-----------|---------------------------------------|-----|
| 34.6.4.1  | VBUS Connection .....                 | 681 |
| 34.6.4.2  | USB3.1/USB2.0 connection.....         | 682 |
| 34.6.4.3  | Power Management Control .....        | 684 |
| 34.6.4.4  | AXI DMA Transfer Control .....        | 695 |
| 34.6.4.5  | List of Interrupt Factors .....       | 706 |
| 34.6.4.6  | Zero Length Packet (ZLP) .....        | 709 |
| 34.6.5    | Examples of software flow .....       | 711 |
| 34.6.5.1  | Outline of software flow .....        | 711 |
| 34.6.5.2  | Initialization .....                  | 712 |
| 34.6.5.3  | Interrupt Process.....                | 714 |
| 34.6.5.4  | Control Transfer .....                | 733 |
| 34.6.5.5  | Bulk Transfer.....                    | 741 |
| 34.6.5.6  | Interrupt Transfer .....              | 758 |
| 34.6.5.7  | DMA Transfer.....                     | 761 |
| 34.6.5.8  | Power Management.....                 | 764 |
| 34.6.5.9  | Device Requests .....                 | 780 |
| 34.6.5.10 | BOT Control .....                     | 789 |
| 34.6.5.11 | The Others .....                      | 792 |
| 34.6.6    | Configuration of USB3PERI.....        | 793 |
| 34.6.6.1  | Prohibitions of Register Access ..... | 793 |
| 34.7      | USB Test Module (USB3TEST) .....      | 794 |
| 34.7.1    | Features .....                        | 794 |

|            |                                                  |      |
|------------|--------------------------------------------------|------|
| Section 35 | PCI Express 2.0 Interface (PCIe).....            | 795  |
| 35.1       | Overview.....                                    | 795  |
| 35.2       | TOP Pins .....                                   | 797  |
| 35.2.1     | Pin Functions .....                              | 797  |
| 35.2.1.1   | List of External Pins .....                      | 797  |
| 35.2.1.2   | List of Internal Pins .....                      | 798  |
| 35.3       | Block Diagram .....                              | 800  |
| 35.3.1     | Reset.....                                       | 800  |
| 35.4       | Register Descriptions (Root Complex Mode).....   | 801  |
| 35.4.1     | List of AXI Bridge Registers .....               | 802  |
| 35.4.2     | List of PCI Express Configuration Registers..... | 807  |
| 35.4.2.1   | Type 1 (for Root Complex) .....                  | 807  |
| 35.4.3     | Register Descriptions (Root Complex Mode) .....  | 809  |
| 35.4.3.1   | AXI Bridge Registers.....                        | 809  |
| 35.4.3.2   | PCI Express Configuration Registers (Type1)..... | 893  |
| 35.5       | Register Descriptions (Endpoint Mode).....       | 954  |
| 35.5.1     | List of AXI Bridge Registers .....               | 955  |
| 35.5.2     | List of PCI Express Configuration Registers..... | 962  |
| 35.5.2.1   | Type 0 (for Endpoint) .....                      | 962  |
| 35.5.3     | Register Descriptions (Endpoint Mode) .....      | 966  |
| 35.5.3.1   | AXI Bridge Registers.....                        | 966  |
| 35.5.3.2   | PCI Express Configuration Registers (Type0)..... | 1049 |
| 35.6       | PHY Register Descriptions .....                  | 1125 |
| 35.7       | Functional Description .....                     | 1125 |

|          |                                                                               |      |
|----------|-------------------------------------------------------------------------------|------|
| 35.7.1   | PCIe Core Functions.....                                                      | 1125 |
| 35.7.2   | Issuing of PCIe Requests and Register Access (by AXI) .....                   | 1126 |
| 35.7.2.1 | PCIe Requests which can be Issued (Supported Commands for TX) .....           | 1126 |
| 35.7.2.2 | Register Access .....                                                         | 1127 |
| 35.7.2.3 | Issuing Memory Requests .....                                                 | 1127 |
| 35.7.2.4 | Issuing Special Requests .....                                                | 1129 |
| 35.7.3   | Initiation of AXI Transactions and Register Access (by PCIe).....             | 1132 |
| 35.7.3.1 | PCIe Requests which can be Received (Supported Commands for RX).....          | 1132 |
| 35.7.3.2 | Initiation of AXI Transactions .....                                          | 1133 |
| 35.7.3.3 | Narrow Transfer .....                                                         | 1134 |
| 35.7.4   | DMAC Functions.....                                                           | 1135 |
| 35.7.4.1 | Register-Type Transfer .....                                                  | 1135 |
| 35.7.4.2 | Descriptor-Type Transfer .....                                                | 1139 |
| 35.7.4.3 | Method of Transfer.....                                                       | 1148 |
| 35.7.4.4 | Inter-Channel Arbitration.....                                                | 1148 |
| 35.7.4.5 | DMA Completed Interrupt .....                                                 | 1149 |
| 35.7.5   | Reception of PCIe Commands .....                                              | 1150 |
| 35.7.5.1 | Reception of MSIs (Root Complex) .....                                        | 1150 |
| 35.7.5.2 | Setting the MSI Window .....                                                  | 1151 |
| 35.7.5.3 | Reception of an Interrupt in Response to a Message Request (Root Complex) ... | 1152 |
| 35.7.5.4 | Reception of Message Requests.....                                            | 1152 |

## Section 1 Overview

This section describes the overview of this LSI.

### 1.1 Features

This LSI chip includes the AI dedicated accelerator (DRP-AI) and 4K-compatible image signal processor (ISP). This processor is vision-AI ASSP for real-time human and object recognition.

The AI dedicated hardware IP, DRP-AI, configured with the dynamic reconfigurable processor (DRP) and AI-MAC, combines both a high-speed AI inference and low power consumption and realizes 1TOPS/W class power performance. In addition, the image signal processor (ISP) is highly robust, producing a stable image independent of the environment, allowing for a high AI recognition accuracy. With these features, this LSI realizes low power consumption, which is a critical factor for embedded devices, making heat dissipation measures easier. The result is that it is ideal for vision AI applications in a wide range of embedded markets, including surveillance security, retail, office automation (OA), industrial automation, and robotics. In addition, this LSI also features abundant high-speed communication interfaces such as USB 3.1, PCI Express®, Gigabit Ethernet, and many CPU peripheral functions, so it can also be used in a variety of applications.

#### ■ CPU and DDR Memory Interfaces

- Cortex®-A53 Dual (996 MHz maximum)
- 32-bit LPDDR4-3200

#### ■ Vision and AI

- AI accelerator: DRP-AI (1.0 TOPS/W class)
- Image signal processor (ISP) with multi-stream capability
- Camera interface: 2× MIPI CSI
- Face and Human Detection Engine

#### ■ Video and Graphics, Display

- H.265/H.264 Multi Codec  
Encoding: H.265 up to 2160p30, H.264 up to 1080p60  
Decoding: H.265 up to 2160p30, H.264 up to 1080p60
- 2D Graphics Engine: 200 MPixels/s
- Display: HDMI 1.4a

#### ■ High Speed Interfaces

- 1× Gigabit Ethernet
- 1× USB3.1 Gen1 Host/Peripheral
- 1× PCIe® Gen 2 (2 lanes)
- 2× SDIO 3.0
- 1× eMMC™ 4.5.1

#### ■ Hardware Security Engine provided

#### ■ Package

- FCBGA (15×15 mm, 0.5-mm pitch)

Figure 1.1-1 Diagram of Functional Overview

## 1.2 Product Lineup

The group currently consists of the following products.

Table 1.2-1 Product Lineup

| Product Part Number | Part Number for Ordering | Package      | Packing         |
|---------------------|--------------------------|--------------|-----------------|
| R9A09G011GBG        | R9A09G011GBG#ACC         | PRBG0841KA-A | Individual tray |
|                     | R9A09G011GBG#BCC         | PRBG0841KA-A | Full carton     |

## 1.3 Functions

Table 1.3-1 Overview of Functions (1/4)

| Item                         | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## 1.5 List of Units

Table 1.5-1 List of Units (1/2)

| Unit Name | Unit Abbreviation*1 | Functional Overview                         |
|-----------|---------------------|---------------------------------------------|
| ADCA      | ATGA                | A/D converter A                             |
| ADCB      | ATGB                | A/D converter B                             |
| AUI       | AUI                 | Audio interface                             |
| CA53      | CA53                | Arm Cortex-A53                              |
| CIF       | CIF                 | CMOS image sensor interface                 |
| CPG       | CPG                 | Clock pulse generator                       |
| CSI       | CSI                 | Clocked serial interface                    |
| CST       | CST                 | Arm CoreSight                               |
| DCU       | DCI                 | Display control unit                        |
| DMAC      | DMAA                | DMA controller                              |
| DRP-AI    | DRPA                | AI accelerator (DRP-AI)                     |
| eMMC      | EMM                 | eMMC host interface                         |
| ETHER     | ETH or ETH0         | Ethernet MAC interface                      |
| GIC       | GIC                 | Generic interrupt controller                |
| GPA       | GPA                 | General processing accelerator              |
| GRP       | GRP                 | 2D graphics engine                          |
| HDMI      | HMI                 | HDMI Tx interface                           |
| ICB       | ICB                 | Interconnect bus                            |
| IIC       | IIC                 | IIC bus interface                           |
| ISP       | ISP                 | Camera ISP                                  |
| JPG       | JPG                 | JPEG codec                                  |
| LPDDR4    | DDR                 | LPDDR4 interface                            |
|           | MMC                 | LPDDR4 memory controller                    |
|           | DDI                 | LPDDR4 PHY interface                        |
| MTD       | FCD                 | Multi-target detection                      |
| PCIe      | PCI                 | PCI Express 2.0 interface                   |
| PFC       | PFC                 | Pin function controller                     |
| PMC       | PMC                 | Internal power domain controller            |
| PWC       | PWC                 | External power sequence controller          |
| PWM       | PWM                 | Pulse-width modulation timer                |
| RAMA      | RAMA                | RAM A                                       |
| RAMB      | RAMB                | RAM B                                       |
| ROM       | ROM                 | ROM                                         |
| RTC       | RTC                 | Real-time clock                             |
| SDI       | SDI                 | SD host interface                           |
| SEC       | SEC                 | Trusted secure IP                           |
| STG       | STG                 | Image sensor timing generator               |
| SYC       | SYC                 | System counter                              |
| SYS       | SYS                 | System configuration                        |
| TIM       | TIM                 | Compare-match timer                         |
| TSU       | TSU                 | Temperature sensor                          |
| UART      | URT                 | Universal asynchronous receiver transmitter |

Table 1.5-1 List of Units (2/2)

| Unit Name | Unit Abbreviation*1 | Functional Overview     |
|-----------|---------------------|-------------------------|
| USB       | USB                 | USB3.1 Gen1 interface   |
| VCD       | VCD                 | H.265/H.264 multi codec |
| WDT       | WDT                 | Watchdog timer          |

Note 1. Used as a prefix for the base address name of a register, terminal name, or signal name.

## Section 2 Pin

This section describes the pins of this LSI.

### 2.1 Pin Assignment

|    | A       | B        | C       | D        | E       | F       | G        | H      | J      | K      | L       | M      | N      | P      | R      | T      | U      | V      | W      | Y      | AA     | AB     | AC     | AD     | AE     | AF     | AG     | AH     | AJ     |      |    |

| GND       | —   | 0           | GND                                                                                                             | —                                  | —                         | —               | —                     | —               | —                               | —               |

Note 1. For 3.3-V input tolerant

Note 2. For the drive strength, see **Section 51.4.2, Standard I/O Characteristics**.

Note 3. These multiplexed pins are for use with the ISP support package, so do not change the multiplexed functional blocks. For details, refer to *RZ/V2M Default Pin Function List*.

Note 4. If PWVBAT is not used, pulled up by PWVDD.

Note 5. Connect an external resistor (1.1kΩ). For details, refer to *the RZ/V2M High-Speed Interface PCB Design Guidelines*.

Note 6. See **Section 2.3, Pin Functions of Functional Blocks** for how to connect the USBVBUS.

Note 7. This pin is intended to be used for LED control during boot sequence. Therefore, do not use this pin for any other purpose.

Note 8. DSMVDD12 can be supplied with 1.2 V by the resistance voltage divider of VDD33. The schematic diagram is shown below.

### Usage Note

In this LSI, supply power to all power pins.

It is necessary to supply power even if the power pin is an unused function and to connect the ground pin to the ground.

## 2.2.2 List of Multiplexed Functional Blocks

- Note 1. The PWISO and RTISO pins are connected to this LSI, and these nodes should be pulled up with a 10kΩ to 100kΩ resistor. The schematic diagram is shown below.

- Note 2. GECLK is the input clock for GEGTXCLK.

- Note 3. Since this LSI has a resistor mounted between the USVBUS pin and GND, connect the pin to the USVBUS pin via a 30-kΩ (±1%) resistor. The schematic diagram is shown below.  
In addition, design so that the voltage is applied to the USVBUS pin after supplying USDVDD, USVP and USVPTX.

Note 4. USOTGID has the internal pull-up resistor.

Note 5. When the power of this LSI is turned off, applying the 3.3-V pull-up voltage in the opposite direction to these pins does not cause any problem.

Note 6. This pin is intended to be used for LED control during boot sequence. Therefore, do not use this pin for any other purpose.

## Section 3 Clock

This section describes the clocks of this LSI.

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 3.1 Overview of Clocks

The clocks which are input to and output from this LSI are divided into the following two types.

- External clocks: Clocks which are externally input to this LSI and those which are externally output from this LSI
- Unit clocks: Clocks for use by the internal units of this LSI

#### 3.1.1 External Clocks

##### 3.1.1.1 Clocks for the Oscillators Circuits (OSC)

This LSI includes two oscillation circuits (OSC) and they are respectively connected to 48 MHz and 32.768 kHz crystals.

**Table 3.1-1** lists the clocks for oscillation circuits. **Figure 3.1-1** shows an example connection of this LSI and the crystals.

Table 3.1-1 List of the Clocks for the Oscillation Circuits (OSC)

| External Pin Name<br>(Multiplexed Pin Name) | I/O    | Function                                                          | Frequency  |
|---------------------------------------------|--------|-------------------------------------------------------------------|------------|
| Clocks for the 32.768 kHz OSC               |        |                                                                   |            |
| RTXIN                                       | Input  | OSC input clock. Connection of a 32.768-kHz crystal is required.  | 32.768 kHz |
| RTXOUT                                      | Output | OSC output clock. Connection of a 32.768-kHz crystal is required. | 32.768 kHz |
| Clocks for the 48 MHz OSC                   |        |                                                                   |            |
| XIN                                         | Input  | OSC input clock. Connection of a 48-MHz crystal is required.      | 48 MHz     |
| XOUT                                        | Output | OSC output clock. Connection of a 48-MHz crystal is required.     | 48 MHz     |

Figure 3.1-1 Example Connection of This LSI and the Crystals

### 3.1.1.2 Pin Functions

The clocks for various external interfaces to be connected to this LSI includes clocks which are externally input to this LSI and clocks which are externally output from this LSI. **Table 3.1-2** lists the clocks for external interfaces. The clocks which are externally output from this LSI are generated by the CPG and output via the units of each interface.

Table 3.1-2 List of External Pins (1/2)

| Pin Name                                    | I/O | Function | Frequency*1 | Supply Source/<br>Destination Unit |
|---------------------------------------------|-----|----------|-------------|------------------------------------|
| CMOS Image Sensor Interfaces                |     |          |             |                                    |
| CMOS image sensor differential input clocks |     |          |             |                                    |
| LVRXCK0P*2                                  | —   | —        | —           | CIF                                |

Note 1. The clock frequencies are either variable or fixed. In the case of the variable clocks, the maximum frequencies which can be output are listed for the output clocks and the maximum frequencies which can be input to this LSI are listed for the input clocks.

Note 2. For more information, contact a Renesas Electronics sales representative.

### 3.1.2 Unit Clocks

The internal units require three types of unit clock. **Table 3.1-3** gives an overview of the types of unit clock.

Table 3.1-3 Overview of the Types of Unit Clock

| Clock Type       | Supply Destination Unit | Overview                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PLL clock        | Other than RTC and PWC  | These are high-speed clocks obtained through frequency-multiplication by the internal PLLs. Most of the clocks distributed to the units are also divided by frequency-dividers. These clocks include those generated by different dividers which are switched by selectors and distributed to the units and those generated by the different PLLs which are switched by selectors and distributed to the units. |
| 48-MHz clock     | Other than RTC and PWC  | The 48-MHz clock which is input externally and signals derived from it by division. That is, these clocks include the 48-MHz-clock itself and those obtained by division by frequency-dividers for distribution and of those, clocks which are switched by selectors for distribution.                                                                                                                          |
| 32.768-kHz clock | RTC, PWC                | The 32.768-kHz clock which is input externally. This is the operating clock of the RTC. The PWC is supplied with clock signals which are obtained by division within the RTC.                                                                                                                                                                                                                                   |

**Table 3.1-4** lists the clocks which are input to and output from each unit. This table lists the supply sources and destinations of the clocks which are input to and output from each unit. The clocks which are supplied to each unit include those supplied by the CPG and those supplied by the other units.

Table 3.1-4 List of Unit Clocks (1/8)

| Unit Clock |           |        |                             | Supply Source/Destination |                  |
|------------|-----------|--------|-----------------------------|---------------------------|------------------|
| Unit       | Clock Pin | I/O    | Frequency [MHz]             | Unit                      | Clock Pin        |
| RTC*3      | —         | —      | —                           | —                         | —                |
| PWC*3      | —         | —      | —                           | —                         | —                |
|            | —         | —      | —                           | —                         | —                |
|            | —         | —      | —                           | —                         | —                |
| CPG        | XINCLK    | Input  | 48                          | External pin              | XIN              |
|            | DETCK     | Input  | 50                          | External pin              | DETCK            |
|            | AUPLLCLK  | Input  | 12.288                      | External pin              | AUPLLCLK         |
|            | AUMCLK    | Output | 12                          | External pin              | AUMCLK           |
|            | GMCLK0    | Output | Max. 100                    | External pin              | GMCLK0           |
|            | GMCLK1    | Output | Max. 100                    | External pin              | GMCLK1           |
| CA53       | CLKIN     | Input  | 996/498/332/249/166/83/41.5 | CPG                       | CA53_CLK         |
|            | APCLK_DBG | Input  | 400/200/100/50/48           | CPG                       | CA53_APCLK_DBG   |
|            | ACLK      | Input  | 400/200/100/50/48           | CPG                       | CA53_ACLK        |
|            | ATCLK     | Input  | 400/200/100/50/48           | CPG                       | CA53_ATCLK       |
|            | TSCLK     | Input  | 48                          | CPG                       | CA53_TSCLK       |
|            | APCLK_REG | Input  | 200/100/50/48               | CPG                       | CA53_APCLK_REG   |

Table 3.1-4 List of Unit Clocks (6/8)

| Unit Clock |           |       |                 | Supply Source/Destination |                 |
|------------|-----------|-------|-----------------|---------------------------|-----------------|
| Unit       | Clock Pin | I/O   | Frequency [MHz] | Unit                      | Clock Pin       |
| TIM10      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[10]     |
| TIM11      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[11]     |
| TIM12      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[12]     |
| TIM13      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[13]     |
| TIM14      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[14]     |
| TIM15      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[15]     |
| TIM16      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[16]     |
| TIM17      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[17]     |
| TIM18      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[18]     |
| TIM19      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[19]     |
| TIM20      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[20]     |
| TIM21      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[21]     |
| TIM22      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[22]     |
| TIM23      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[23]     |
| TIM24      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[24]     |
| TIM25      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[25]     |
| TIM26      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[26]     |
| TIM27      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[27]     |
| TIM28      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[28]     |
| TIM29      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[29]     |
| TIM30      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[30]     |
| TIM31      | PCLK      | Input | 100/50/48       | CPG                       | CPERI_GRPB_PCLK |
|            | INCLOCK   | Input | 2               | CPG                       | TIM_CLK[31]     |

Table 3.1-4 List of Unit Clocks (7/8)

| Unit Clock         |           |       |                 | Supply Source/Destination |             |
|--------------------|-----------|-------|-----------------|---------------------------|-------------|
| Unit               | Clock Pin | I/O   | Frequency [MHz] | Unit                      | Clock Pin   |
| TSU0               | PCLK      | Input | 48              | CPG                       | TSU0_PCLK   |
| TSU1               | PCLK      | Input | 48              | CPG                       | TSU1_PCLK   |
| UART0              | PCLK      | Input | 100/50/48       | CPG                       | URT_PCLK    |
|                    | SCLK      | Input | Max. 108/48     | CPG                       | URT_CLK[0]  |
| UART1              | PCLK      | Input | 100/50/48       | CPG                       | URT_PCLK    |
|                    | SCLK      | Input | Max. 108/48     | CPG                       | URT_CLK[1]  |

[illegible]

Note 1. This pin functions as an output in actual operation.

Note 2. P0\_CLK and P1\_CLK of CIF are controlled and supplied by the Clock Gating cells within the CIF.

Note 3. For more information, contact a Renesas Electronics sales representative.

## 3.2 Clock System Diagram

For the clock system diagram, see the section of CPG.

## 3.3 Clock Configuration of CPG

All units excluding RTC\*<sup>1</sup> and PWC\*<sup>2</sup> of this LSI are configured to supply the clock signal from the CPG. The CPG has the following functionality to control the clock signal for supply to a given unit.

- Six PLLs
- Dividers
- Clock selectors
- Clock Gating cells

**Note 1.** The RTC runs on the 32.768-kHz clock which is input externally.

**Note 2.** The PWC runs on a frequency-divided clock supplied from the RTC.

**Figure 3.3-1** shows a schematic view of the clock configuration of this LSI.

Figure 3.3-1 Schematic View of the Clock Configuration

## 3.4 Clock Function

### 3.4.1 PLLs

This LSI includes six PLLs. The PLLs multiply externally input 48-MHz clocks as reference signals to generate high-speed clocks. Each PLL can change the operating mode and the oscillation frequency.

**Table 3.4-1** lists the types of PLLs of this LSI and their main usages.

Table 3.4-1 Types and Usages of PLLs

| PLL Name | SSCG Setting                                  | Main Usage             |
|----------|-----------------------------------------------|------------------------|
| PLL1     | SSCG is available (default SSCG included)     | Dedicated for CA53     |
| PLL2     | SSCG is available (default SSCG included)     | For SYSTEM BUS and ISP |
| PLL3     | SSCG is available (default SSCG included)     | Dedicated for LPDDR4   |
| PLL4     | SSCG is not available                         | For STG and ADC        |
| PLL6     | SSCG is available (default SSCG not included) | For DRP-AI             |
| PLL7     | SSCG is available (default SSCG included)     | For display control    |

### 3.4.2 Dividers and Clock Selectors

Dividers and clock selectors are located in a later stage of the PLL.

There are two types of dividers, a fixed divider where the frequency divisor is fixed and a variable divider which can change the frequency divisor.

### 3.4.3 Clock Gating Cells

Clock Gating cells are located on a part of the clock output paths, which can control supplying and stopping of the clock signal.

## Section 4 Reset

This section describes resets of this LSI.

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 4.1 Overview of Resets

#### Classification of Resets

The reset functions of this LSI are classified into three categories: hardware resets, watchdog timer reset, and software resets. **Table 4.1-1** lists the classification of resets. For details, see the section of CPG.

Table 4.1-1 Classification of Resets

| Category                                     | Sub-Category                | Reset Source                         | Scope                           |
|----------------------------------------------|-----------------------------|--------------------------------------|---------------------------------|
| Hardware resets<br>(External pin resets)     | Single resets               | RTRSTN pin                           | RTC                             |
|                                              |                             | PWRSTN pin                           | PWC                             |
|                                              | System resets               | RSTN pin                             | All units excluding RTC and PWC |
| Watchdog timer reset                         |                             | Counter overflow                     | All units excluding RTC and PWC |
| Software resets<br>(register control resets) | CPG register control reset  | CPG register control                 | Target units set by registers   |
|                                              | CA53 register control reset | CA53 register control                | CA53                            |
|                                              | Resets within the units     | Control of individual unit registers | Functions within the units      |

## 4.2 Configuration of Resets

### 4.2.1 Configuration of Hardware Resets (External Pin Resets)

**Table 4.2-1** lists the names and functions of the external pins for a hardware reset.

For the connection configuration (example of connection) of the external pin resets, see **Figure 4.2-1**.

Table 4.2-1 Hardware Reset Pin Functions

| Pin Name                                                                             | I/O    | Function                                                                                 | Active Level | Connected Unit |
|--------------------------------------------------------------------------------------|--------|------------------------------------------------------------------------------------------|--------------|----------------|
| Single reset for external pins: Reset range is RTC single reset and PWC single reset |        |                                                                                          |              |                |
| RTRSTN                                                                               | Input  | Input reset of the RTC section                                                           | Low          | RTC            |
| PWRSTN                                                                               | Input  | Input reset of the PWC section                                                           | Low          | PWC            |
| Reset for external RSTN pin: Reset range is system reset                             |        |                                                                                          |              |                |
| RSTN                                                                                 | Input  | System input reset                                                                       | Low          | CPG            |
| PWSYSRSTN                                                                            | Output | System reset output. Connected to the RSTN pin to use the power control function of PWC. | —            | PWC            |

**Figure 4.2-1** shows an example of connection of the external pin resets (while a debugger is connected).

Figure 4.2-1 Example Connection of the External Pin Resets (while a Debugger is Connected)

### CAUTION

RSTN, DESRSTN, and DETRSTN should be asserted for no less than 10  $\mu$ s. When a system reset is initiated by RSTN, DESRSTN, or DETRSTN, the external power switch of PD\_MEM is also turned off. Accordingly, secure the period for assertion of RSTN, DESRSTN, and DETRSTN, so that the power supply voltage of PD\_MEM falls below 0.1 V within 10  $\mu$ s or to continue until the power supply voltage falls below 0.1 V. In addition, to switch the power supply for PD\_MEM on or off by using the external power switch, make sure that the power supply voltage is cut off within the above period or secure enough time for the assertion of RSTN, DESRSTN, and DETRSTN so that the power supply voltage has been cut off.

### 4.2.2 Configuration of Watchdog Timer Reset

A reset request signal from the WDT (WDTRSTB) is connected to a WDT timeout reset pin (WDT\_RST\_N[n] (n = 0, 1) of the CPG. If WDTRSTB on either pin is asserted, this LSI is system-reset.

### 4.2.3 List of Unit Resets

Control over the resetting of individual units is possible by setting registers of the CPG by software. **Table 4.2-2** lists the correspondence between the reset pins of individual units and the sources for supply of the resets.

Table 4.2-2 List of Unit Resets (1/3)

| Unit Reset |                  | Supply Source |                     |
|------------|------------------|---------------|---------------------|
| Unit       | Reset Pin        | Unit          | Reset Pin           |
| CA53       | ARESETn          | CPG           | CA53_NARESET        |

Note 1. For more information, contact a Renesas Electronics sales representative.

## 4.3 Reset System Diagram

For the reset system diagram, see the section of CPG.

## 4.4 Reset Functions

### 4.4.1 Hardware Resets (External Pin Resets)

These resets are initiated by external pins of the LSI.

The units to be reset depend on the reset pin through which control is applied.

#### 4.4.1.1 Single Resets

A few units can be individually reset. For details, refer to the description of CPG.

##### (1) RTC and PWC Resets

The RTRSTN and PWRSTN pins are dedicated for resetting of the RTC and PWC, respectively. These reset pins must be controlled by the external circuits of this LSI.

**Table 4.4-1** lists the sources of the single resets and the respective timings for release from reset.

Table 4.4-1 Single Reset Control

| Category  | Source<br>(Reset Pin State) | Reset Release Timing                                                                                | Scope |
|-----------|-----------------------------|-----------------------------------------------------------------------------------------------------|-------|
| RTC reset | RTRSTN pin = Low            | After 1.5-V power is supplied to the I/O section of RTC and 0.8-V power is supplied to the RTC core | RTC   |
| PWC reset | PWRSTN pin = Low            | After 1.8-V power is supplied to the I/O section of PWC and 0.8-V power is supplied to the PWC core | PWC   |

#### 4.4.1.2 System Reset

##### (1) System Reset in Normal Mode

The RSTN pin controls a system reset.

**Table 4.4-2** lists the sources of a system reset by the pins and the timing for release from reset.

Table 4.4-2 System Reset: Control Pins

| Category     | Source<br>(Reset Pin State) | Reset Release Timing                                       | Scope                                       |
|--------------|-----------------------------|------------------------------------------------------------|---------------------------------------------|
| System reset | RSTN pin = Low              | After the external power supplies of the LSI are turned on | All units of this LSI excluding PWC and RTC |

By connecting the output signal on the PWCSYSRSTN pin to the RSTN pin, the LSI can be released from the reset state in response to the completion of the external power supplies being turned on (the PWCSYSRSTN pin outputs the low level while the external power supplies are turned on and is placed in the Hi-Z state after the completion of the external power supplies being turned on). Note that the RSTN pin is provided with a pull-up resistor within the LSI.

#### 4.4.2 Watchdog Timer Reset

A watchdog timer reset is automatically initiated by the hardware of this LSI when the counter of the watchdog timer of this LSI detects an overflow\*1. After an interrupt request signal is generated, deassert the interrupt signal of the watchdog timer by software until the next time the counter overflows

**Note 1.** After an interrupt request signal is generated in every period set in the counter of the watchdog timer, the interrupt signal is not asserted and the counter overflows next time.

#### 4.4.3 Software Resets

A software reset involves the initialization in response to a register setting.

There are four types of software reset listed below.

- Reset for initializing the target units by setting registers in the CPG.
- Reset for initializing CA53 by setting registers in CA53
- Reset for initializing the functions within the units individually by setting registers in other units

# Section 5 Interrupt

This section describes the interrupt function of this LSI.  
This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

## 5.1 Interrupt System Diagram

This LSI is equipped with a GIC (GIC-400) as an interrupt controller for CA53. Signals from respective units and external interrupts are input via a synchronization circuit and a GIC (GIC-400).

Figure 5.1-1 shows the interrupt system diagram of this LSI.

Figure 5.1-1 Interrupt System Diagram

### NOTE

For details on the interrupt control (controlling the interrupt controller), see the GIC section.  
However, as the following units are for use with the ISP support package, do not use the registers of the GIC related to the target channels.

| Unit Name | Resource for Use with ISP Support Package                 | Unit Name | Resource for Use with ISP Support Package |
|-----------|-----------------------------------------------------------|-----------|-------------------------------------------|
| TIM       | Total of 16 channels, ch. 0 to ch. 7 and ch. 24 to ch. 31 | JPG       | —                                         |
| PWM       | Total of 9 channels, ch. 0 to ch. 7 and ch. 15            | MTD       | —                                         |
| DMAC      | Total of 8 channels, DMAC1 ch. 0 to ch. 7                 | AUI       | —                                         |
| UART      | Ch. 1                                                     | ADCA      | —                                         |
| IIC       | Total of 2 channels, ch. 1 and ch. 3                      | ADCB      | —                                         |
| CSI       | Total of 4 channels, ch. 1 to ch. 3 and ch. 5             | DCU       | —                                         |
| WDT       | Ch. 1                                                     | HDMI      | —                                         |
| GRP       | —                                                         | STG       | —                                         |
| VCD       | —                                                         | ISP/GPA   | —                                         |

## 5.2 Synchronization and Polarity of Interrupts

The input specifications of the GIC are shown below.

- PPI (private peripheral interrupt): Active-low level interrupt
- SPI (shared peripheral interrupt): Active-high level interrupt or rise-edge pulse interrupt

To satisfy this specification, the interrupt signals from the various units are polarity-matched and synchronized.

**Figure 5.2-1** shows a functional overview of the synchronization circuit.

Figure 5.2-1 Functional Overview of the Synchronization Circuit

## 5.3 Interrupt Settings

Some units always require register settings for level or pulse mode and the active level of the interrupt.

### 5.3.1 Level/Pulse Mode Setting

The interrupt outputs of the units listed in **Table 5.3-1** require the selection of level or pulse mode by the register of the respective units.

This interrupt should be used with the settings listed in the table.

Table 5.3-1 Interrupt Signals with Switching Function between Level Mode and Pulse Mode

| Unit Name | Interrupt Output Pin Name | Description                   |
|-----------|---------------------------|-------------------------------|
| DMAC      | DMAINT[15:0]              | Set it to level mode for use. |
|           | DMAERR                    | Set it to level mode for use. |
| TIM0-31   | INTCMD                    | Set it to level mode for use. |

#### NOTE

The interrupt output mode for units other than listed in **Table 5.3-1** is fixed. (Level or pulse mode cannot be selected.)  
For details on register settings, see the DMAC section and TIM section.

### 5.3.2 Active Level Setting

For interrupts input from the external interrupt pin INEXINTn (n: 0 to 38), the active level can be selected by the register in the PFC unit.

The active level of the interrupt input pins should be set and used according to the interrupt specifications of the external device.

For details on the settings, see the PFC section.

## 5.4 List of Interrupts

**Table 5.4-1** is the list of GIC interrupts.

Set the interrupts (level or pulse interrupts) for the interrupt controller as shown in the table.

### 5.4.1 List of CA53 Interrupts

**Table 5.4-1** lists the interrupt ID assignment information for the GIC (GIC-400 for CA53).

The following table shows the correspondence between the interrupt input pins of the GIC and the interrupt outputs notified to the GIC from individual units.

Table 5.4-1 Interrupt list of GIC (GIC-400 for CA53) (1/10)

| PPI/<br>SPI | ID | GIC Input Pin Name | Interrupt Request Source |                    |                                                                 |                 |              |
|-------------|----|--------------------|--------------------------|--------------------|-----------------------------------------------------------------|-----------------|--------------|
|             |    |                    | Unit                     | Output Pin Name    | Interrupt Description                                           | Level/<br>Pulse | Active Level |
| PPI         | 26 | nCNTHPIRQ[0]       | CA53                     | nCNTHPIRQ[0]       | Hypervisor physical timer interrupt [Core0/Core1]               | Level           | Low          |
|             |    | nCNTHPIRQ[1]       |                          | nCNTHPIRQ[1]       |                                                                 |                 |              |
|             | 27 | nCNTVIRQ[0]        | CA53                     | nCNTVIRQ[0]        | Virtual timer event [Core0/Core1]                               | Level           | Low          |
|             |    | nCNTVIRQ[1]        |                          | nCNTVIRQ[1]        |                                                                 |                 |              |
|             | 28 | nLEGACTFIQ[0]      | PMC                      | INT_CA53_LFIQ_N[0] | Cortex-A53 standby release signal [Core0/Core1]<br>(Legacy FIQ) | Level           | Low          |

|             | 426 | IRQS[394]             |                          | EC7TIOVF        | ECC error address capture overflow interrupt | Pulse           | Rise            |

Note 1. Make sure to set the registers for the interrupt output mode and active level by referring to **Section 5.3, Interrupt Settings**.

Note 2. This register is for use with the ISP support package. Therefore, using this interrupt is prohibited.

Note 3. For more information, contact a Renesas Electronics sales representative.

## Section 6 Address Map

This section describes the address space of this LSI.

### 6.1 Overall Address Map

**Figure 6.1-1** shows the address map of this LSI, which has a 34-bit address space (16 GB).

Note that the upper 8 GB of the address space is a reserved area.

The address space contains the following areas.

- Slave area: 1-GB space from 00\_8000\_0000h to 00\_BFFF\_FFFFh  
The areas of the individual units are allocated.  
For details of the slave area, see **Section 6.2, Address Map Details**.
- PCIe area: 1-GB space from 00\_C000\_0000h to 00\_FFFF\_FFFFh  
(PCIe window access area)
- DDR area 1-S: 2-GB space from 00\_0000\_0000h to 00\_7FFF\_FFFFh\*<sup>1</sup>  
(the lower 2 GB of addresses in the externally connected LPDDR4 memory)
- DDR area 1-M: 2-GB space from 01\_0000\_0000h to 01\_7FFF\_FFFFh\*<sup>1</sup>  
(a mirrored area for DDR area 1-S, that is, for the lower 2 GB of addresses in the externally connected LPDDR4 memory)
- DDR area 2: 2-GB space from 01\_8000\_0000h to 01\_FFFF\_FFFFh\*<sup>1</sup>  
(the upper 2 GB of addresses in the externally connected LPDDR4 memory)

**Note 1.** The following register must be set to suit the configuration of the externally connected LPDDR4 memory.

1) LPDDR4 memory size setting (set in the `Sche_DeviceSize` register of the ICB)

For details, see the section of ICB.

Figure 6.1-1 Overall Address Space

## 6.2 Address Map Details

**Table 6.2-1** lists the allocation of the address spaces of this LSI to the units.

For those units which have multiple address spaces, the usage is indicated in the “Supplementary Note” column. The “Base Address Name” column indicates the correspondence with the port names of the AXI, AHB, and APB slaves allocated by the ICB.

Table 6.2-1 Address Allocation Details (1/5)

| Base Address  | Size*2 |        | Unit     | Base Address Name | Supplementary Note          | Remarks |
|---------------|--------|--------|----------|-------------------|-----------------------------|---------|
| 00_0000_0000h | 2      | Gbytes | MMC      | —                 | LPDDR4 (less than 2 Gbytes) | —       |
| 00_8000_0000h | 128    | Kbytes | ROM      | ROM_S0_base       | ROM memory                  | —       |

Note 1. Access to the reserved address areas is prohibited.

Note 2. If a slave unit does not have an address range equivalent to the allocated size, the remainder of the area is viewed as a mirrored area. Access to the mirrored area is prohibited.

## 6.3 Access to 34-Bit Address Space

**Table 6.3-1** lists the classification of the areas accessible by the units which have a master port.

Table 6.3-1 Classification of Areas Accessible by the Units

| Unit Category                                                             | Target Unit                                                                                                 |
|---------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| Units which can access a 34-bit space<br>(00_0000_0000h to 01_FFFF_FFFFh) | CA53, CST                                                                                                   |
|                                                                           | <b>[Units which require bank switching]*1</b><br>DRP-AI, eMMC, SDI0, SDI1, ETHER, PCIe, USB, VCD, GRP, DMAC |

Note 1. Bank switching will allow access to DRP-AI, eMMC, SDI0, SDI1, ETHER, PCIe, USB, VCD, GRP, and DMAC. The units which require bank switching must access the address space over 32 bits by setting the register of SYS (bank switching is described in the next section).

## 6.4 Access by Bank Switching

The address width of the master port of the target units listed below is 32 bits (4-GB address spaces).

Therefore, in this LSI, to make the 34-bit address space (16-GB address space) accessible, extended addresses (bank addresses) are provided by using the two higher-order bits for access through bank switching.

The bank address is switched by using the bank address switching register in SYS.

**Table 6.4-1** lists the correspondence between the bank addresses and the address spaces.

For the bank address switching register in SYS, see the section of SYS.

Target units: DRP-AI, eMMC, SDI0, SDI1, ETHER, PCIe, USB, VCD, GRP, DMAC

Table 6.4-1 Correspondence between the Bank Addresses and the Address Spaces

| Bank Address<br>(Two Extension Bits) | Address Space                                               |
|--------------------------------------|-------------------------------------------------------------|
| 11b                                  | 03_0000_0000h to 03_FFFF_FFFFh (4 GB)<br>Setting prohibited |
| 10b                                  | 02_0000_0000h to 02_FFFF_FFFFh (4 GB)<br>Setting prohibited |
| 01b                                  | 01_0000_0000h to 01_FFFF_FFFFh (4 GB)                       |
| 00b                                  | 00_0000_0000h to 00_FFFF_FFFFh (4 GB)                       |

### CAUTION

Any access that spans 32-bit address boundaries is prohibited.

The usage of the value of the bank address switching register in SYS (the address extension method) differs between the DMAC and other units. **Figure 6.4-1** and **Table 6.4-2** give summaries of address extension.

Table 6.4-2 Summary of the 34-Bit Address Extension Method

| Address Extension Method | Target Unit and Summary of the Address Extension Method                                                                                   |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| Address extension 1      | DRP-AI, eMMC, SDIO, SDI1, ETHER, PCIe, USB, VCD, GRP<br>⇒ The address is extended by the output of two bank address bits from SYS to ICB. |
| Address extension 2      | DMAC<br>⇒ The address is extended by the output of two bank address bits from SYS to DMAC.                                                |

Figure 6.4-1 Schematic Diagram of the 34-Bit Address Extension Method

To switch the bank address, follow the procedure below before starting access by the master port.

For the bank address switching register in SYS, see the section of SYS.

[Bank Address Switching Procedure in Outline]

- Step 1. Set the bank address switching register of SYS.\*1
- Step 2. Wait for at least 50 ns.\*2
- Step 3. Start access with the set bank address.

**Note 1.** If the target unit is DRP-AI, eMMC, SDIO, SDI1, ETHER, PCIe, USB, VCD, or GRP, change the bank address while the target master port is stopped or idle, i.e., while it is not proceeding with access through buses. If the target unit is DMAC, change the bank address while operation of the target channels is stopped.

**Note 2.** The bank switching register requires 50 ns from writing until the setting is reflected.

### 6.4.1 Address Extension 1

For DRP-AI, eMMC, SDIO, SDI1, ETHER, PCIe, USB, VCD, and GRP, the two bank address bits from SYS are extended by the higher-order bits [33:32] from the 32 address bits [31:0] of each master port to configure the address bus of the ICB. See **Figure 6.4-1** for the schematic diagram of address extension 1.

The following describes an example of the bank address switching procedure for the unit for address extension 1.

#### ■ For ETHER

- Step 1. Change the operating mode of ETHER to reset mode.
- Step 2. Set the bank address in bits 1 and 0 of the PERI1\_BANK register in SYS.
- Step 3. Read the register value set in step 2 to check that the value has been reflected.
- Step 4. Make initial settings for ETHER ("X" of register values should be specified by the user).
  - Poll the CSR register (00Ch) until it becomes 0000\_0000h (reset mode).
  - Write 0000\_0001h to the CCC register (set to config mode).
  - Poll the CSR register (00Ch) until it becomes 0000\_0002h (config mode).
  - Write 0000\_000Xh to the CXR2C register (52Ch).
  - Write 0000\_2000h to the CXR2A register (508h) (set the maximum frame size to 8 KB).
  - Write 0000\_XXXXh to the CXR71 register (554h).
  - Write XXXX\_XXXXh to the CXR24 register (5C0h).
  - Write 0000\_XXXXh to the CXR25 register (5C8h).
  - Write 0000\_00XXh to the CXR22 register (518h).
  - Write 0000\_000Xh to the CXR2D register (5B0h).
  - Write XXXX\_XXXXh to the DBAT register (004h).
  - Write XXXX\_00XXh to the RCR register (090h).
  - Write 0FFC\_0FFCh to the RTC register (0B4h) (set the maximum reception frame size to 4092 bytes).
  - Write 000X\_0X0Xh to the CIE register (384h).
  - Write 0000\_XXXXh to the DIE register (450h).
  - Write 0000\_0XXXh to the EIE register (458h).
  - Write 000X\_XXXXh to the RIE0 register (460h).
  - Write X00X\_XXXXh to the RIE1 register (468h).
  - Write X00X\_XXXXh to the RIE2 register (470h).
  - Write 000X\_0X0Xh to the TIE register (478h).
  - Write 000X\_XXXXh to the RIE3 register (488h).
  - Write 0X0X\_00X2h to the CCC register (000h) (set to operation mode).
  - Write 0XXX\_XXXXh to the CXR20 register (500h).
  - Write 000X\_0X03h to the TCCR register (304h).

### 6.4.2 Address Extension 2

The DMAC is provided with an address width extension function within the unit by using the value of the bank address switching register of SYS, which realizes extension into the 34-bit space (16 GB).

The bank address from SYS is appended to the 32-bit addresses output by the general-purpose DMAC of DMA for output to the ICB in the 34-bit address width.

The bank address switching address register of SYS provides three types of bank address, respectively for the descriptor, source, and destination per DMAC number and channel. The descriptor, source, and destination areas can be set individually in each 4-GB space by selecting the required bank address of the two higher-order bits in utilizing the AXI ID information when a given channel proceeds with access through the AXI bus.

**Figure 6.4-2** shows a schematic of the address extension function of the DMAC.

Figure 6.4-2 Schematic of Address Bus Width Extension (Address Extension 2)

**Table 6.4-3** lists the AXI ID information for access by the DMAC through the AXI bus.

**Table 6.4-4** describes how a given channel selects the bank address by using the AXI ID information.

Table 6.4-3 AXI ID Information of DMAC

| Unit Name | Macro Name | AXI ID[4]                          | AXI ID[3]               | AXI ID[2] | AXI ID[1] | AXI ID[0] |
|-----------|------------|------------------------------------|-------------------------|-----------|-----------|-----------|
| DMAC      | DMAC0      | Descriptor access/<br>DMA transfer | Channel number of DMAC0 |           |           | 0         |
|           | DMAC1      | Descriptor access/<br>DMA transfer | Channel number of DMAC1 |           |           | 1         |

**Note:** The DMAC includes two units. DMAC0 and DMAC1 have eight channels respectively, 16 channels in total.

Table 6.4-4 DMAC Bank Address Selection Specification

| Unit Name    | Source Reading<br>Descriptor Reading                             | Destination Writing<br>Descriptor Write-Back                     |
|--------------|------------------------------------------------------------------|------------------------------------------------------------------|
| DMAC0, DMAC1 | The two higher-order bits of MARADDR are selected by AXI ID[4:1] | The two higher-order bits of MAWADDR are selected by AXI ID[4:1] |

The following describes the selection of bank addresses with the AXI ID information, taking DMAC0 as an example.

The bank addresses listed below are input from SYS to DMAC0 (the following are the internal pin names of DMAC0).

When a given channel proceeds with access through AXI, the one higher-order bits of MARADDR are selected by AXI ID[4:1] for source reading and descriptor reading, and the two higher-order bits of MAWADDR are selected by AXI ID[4:1] for destination writing and descriptor write-back.

Table 6.4-5 Selection of MARADDR and MAWADDR for DMAC0

| AXI ID[4] | AXI ID[3:1] | Selected MARADDR Higher-Order Address | Selected MAWADDR Higher-Order Address |
|-----------|-------------|---------------------------------------|---------------------------------------|
| 0b        | 000b        | Channel 0 source address              | Channel 0 destination address         |
| 0b        | 001b        | Channel 1 source address              | Channel 1 destination address         |
| 0b        | 010b        | Channel 2 source address              | Channel 2 destination address         |
| 0b        | 011b        | Channel 3 source address              | Channel 3 destination address         |
| 0b        | 100b        | Channel 4 source address              | Channel 4 destination address         |
| 0b        | 101b        | Channel 5 source address              | Channel 5 destination address         |
| 0b        | 110b        | Channel 6 source address              | Channel 6 destination address         |
| 0b        | 111b        | Channel 7 source address              | Channel 7 destination address         |
| 1b        | 000b        | Channel 0 descriptor address          | Channel 0 descriptor address          |
| 1b        | 001b        | Channel 1 descriptor address          | Channel 1 descriptor address          |
| 1b        | 010b        | Channel 2 descriptor address          | Channel 2 descriptor address          |
| 1b        | 011b        | Channel 3 descriptor address          | Channel 3 descriptor address          |

The following describes an example of the bank address switching procedure for DMAC.

- Step 1. Check that bit 0 (EN) and bit 2 (TACT) in the CHSTAT\_n register of DMAC are 0b.  
(n = channel for which the bank address is to be changed)
- Step 2. Set the bank address in the SYS\_DMAAm\_CHn\_BANK register.  
(m = 0, 1; n = 01, 23, 45, 67)
- Step 3. Read the register value set in step 2 to check that the value has been reflected.
- Step 4. Make transfer settings for the DMAC unit and channels for which the bank address has been changed and start DMA transfer.

For details of DMA transfer control, see the section of DMAC.

For details of the SYS registers, see the section of SYS.

## Section 7 Bus Structure

This section describes the bus structure of this LSI.

For details on the functions of the interconnect bus (ICB), see the section on ICB.

### 7.1 Bus Connection Configuration

Figure 7.1-1 shows the connection configuration of the ICB and various units.

Figure 7.1-1 Bus Connection Configuration

**Figure 7.2-1** shows the access path between masters and slaves of the units included in this LSI.

(Continuation of the previous page)

**Note 1.** Access not listed in **Figure 7.2-1** is prohibited.

**Note 2.** The following accesses shown in **Figure 7.2-1** are for the ISP support package and should not be used.

- Access to the slave port with \*1
- Access from the master port with \*2
- Access to the slave ports of the following channels with \*3
  - TIM: Total of 16 channels, ch. 0 to ch. 7 and ch. 24 to ch. 31
  - PWM: Total of 8 channels, ch. 0 to ch. 7
  - WDT: Ch. 1
  - CSI: Total of 4 channels, ch. 1 to ch. 3, ch. 5
  - IIC: Total of 2 channels, ch. 1 and ch. 3
  - UART: Ch. 1
  - DMAC: Total of 8 channels, DMAC1 ch. 0 to ch. 7
- Access from the master ports of the following channels with \*4
  - DMAC: Total of 8 channels, DMAC1 ch. 0 to ch. 7

Figure 7.2-1 Bus Access Path

### 7.3 Master and Slave Port Specifications

For details on the master port and slave port specifications, see the section on ICB.

## Section 8 Power Supply

This section describes the power supply of this LSI.

### 8.1 External Power Supply Pins

The external power supplies of this LSI are described below. The following five power supply systems require external power sources.

- RTC power supplies: Power supplies for the RTC (1.5 V, 0.8 V)
- PWC power supplies: Power supplies for the PWC (1.8 V, 0.8 V)
- Internal power supplies: Power supplies for the internal logic cells and SRAM and ROM (0.8 V)
- I/O power supplies: Power supplies for the I/O cells (1.8 V/3.3 V)
- IP power supplies: Power supplies for the IP cores (0.8 V/1.1 V/1.2 V/1.8 V/3.3 V)

Note that the individual external power supplies of this LSI need to be turned on and off in specified sequences and these are controlled by the hardware of the PWC. **Figure 8.1-1** is a schematic view of the control of external power supplies by the PWC. For details, see the section of PWC.

Figure 8.1-1 Schematic View of the Control of External Power Supplies by the PWC

#### NOTE

When the RSTN pin is to be controlled externally from the LSI, connect the PWSYSRSTN pin and the RSTN pin in parallel to GND via a switch.

Table 8.1-1 Definitions of the States of External Power Supplies

| Power Supply State Definition | RTC Power Supply | PWC Power Supply | Internal Power Supply | I/O Power Supply | IP Power Supply |
|-------------------------------|------------------|------------------|-----------------------|------------------|-----------------|
| All power supplies off        | OFF              | OFF              | OFF                   | OFF              | OFF             |
| Backup power supply on        | ON               | OFF              | OFF                   | OFF              | OFF             |
| PWC supply on                 | ON               | ON               | OFF                   | OFF              | OFF             |
| All power supplies on         | ON               | ON               | ON                    | ON               | ON              |

Although the PWC unit is for controlling the external power supplies, an external PMIC (power management IC) and such can be used instead of the PWC to control the external power supplies to this LSI. **Figure 8.1-2** shows an example of external connections when the PWC is not to be used.

Figure 8.1-2 Example of External Connections when the PMIC is Used

Since the PWC of this LSI is recommended, the use of the PWC is assumed in subsequent descriptions of the power supply specifications.

## 8.2 Internal Power Domains

This section describes the specifications of the internal power supplies (power domains) of this LSI.

### 8.2.1 Definitions of the Power Domains

**Table 8.2-1** lists the correspondence between the definitions of the internal power domains of the LSI and the units which belong to the respective power domains.

For PD\_MEM, PD\_VIDEO0, PD\_VIDEO1, PD\_RFX, PD\_DRPA, and PD\_CA53, control in the form of switching the power on or off is possible. Switching the power on or off is controlled by setting registers of the PMC.

For details, see the section of PMC.

Table 8.2-1 Definitions of the Power Domains and the Units which belong to the Respective Power Domains

| Power Domain Control Unit | Power Domain Name | Target Unit*1                                                                                             | Remarks                              |
|---------------------------|-------------------|-----------------------------------------------------------------------------------------------------------|--------------------------------------|
| —                         | PD_AWO            | Units in the internal power supply area other than PD_MEM, PD_VIDEO0, PD_VIDEO1, PD_RFX, PD_DRPA, PD_CA53 | Internal power supply (0.8-V) area   |
| PMC                       | PD_MEM            | LPDDR4 (MMC, DDI), ICB (Scheduler)                                                                        |                                      |
|                           | PD_VIDEO0         | STG, ISP, GPA                                                                                             |                                      |
|                           | PD_VIDEO1         | VCD, JPG, ISP, GPA                                                                                        |                                      |
|                           | PD_RFX            | RAMB                                                                                                      |                                      |
|                           | PD_DRPA           | DRP-AI                                                                                                    |                                      |
|                           | PD_CA53           | CA53                                                                                                      |                                      |
| —                         | PD_RTC            | RTC                                                                                                       | RTC power supply (1.5-V, 0.8-V) area |
| —                         | PD_PWC            | PWC                                                                                                       | PWC power supply (1.8-V, 0.8-V) area |

Note 1. For details of the target units which belong to the respective power domains, see **Table 8.2-2**.

8.2.2 Power Domain Diagram

Figure 8.2-1 shows the configuration of the power domains of this LSI.

Figure 8.2-1 Power Domain Diagram

### 8.2.3 Correspondence between Power Domains and Units

**Table 8.2-2** lists the correspondence between the power domains and the units.

Table 8.2-2 Correspondence between Power Domains and Units

| Power Domain Name | Unit Name   | Power Domain Name | Unit Name     |
|-------------------|-------------|-------------------|---------------|
| PD_AWO            | CST         | PD_MEM            | LPDDR4        |
|                   | DMAC        |                   | ICB (PD_MEM)  |

|                   | ICB(REG)    |                   |               |
|                   | ICB(PD_AWO) |                   |               |

## 8.2.4 Internal Power Domains

The internal cell areas which operate with internal power supplies (0.8 V) are in seven different power domains.

All but one of the power domains are configured so that power can be turned off by using an external switch (for one domain) and the internal power switches of the LSI to control the supply of 0.8-V power. **Table 8.2-3** lists the internal power domains and the power switches and **Figure 8.2-2** is a schematic view of the allocation of the internal power domains and the power switches.

Table 8.2-3 Power Switches Used for the Respective Power Domains

| Power Domain Name | Power Switch                     | Remarks                                                                       |
|-------------------|----------------------------------|-------------------------------------------------------------------------------|
| PD_AWO            | —                                | Always on when 0.8-V power is supplied.                                       |
| PD_MEM            | External power switch of the LSI | Switching the power off with an external power switch of the LSI is possible. |
| PD_VIDEO0         | Internal power switch of the LSI | Switching the power off with an internal power switch of the LSI is possible. |
| PD_VIDEO1         | Internal power switch of the LSI |                                                                               |
| PD_RFX            | Internal power switch of the LSI |                                                                               |
| PD_DRPA           | Internal power switch of the LSI |                                                                               |
| PD_CA53           | Internal power switch of the LSI |                                                                               |

**Note:** These switches are designed to allow turning power off to achieve lower power consumption for the chip while the external power is being supplied, reducing circuit leakage current in the specified power domains.

Figure 8.2-2 Schematic View of the Allocation of the Internal Power Domains and the Power Switches

## Section 9 System Function

This section describes the system function.

### 9.1 System Startup/Shutdown

#### 9.1.1 System Startup

This LSI starts the system boot process when the PWC is powered on and the reset is released.

**Figure 9.1-1** shows the operation of the individual units in the system startup process.

The RTC, PWC, and CPG are involved in the system startup process, and the startup process is executed by the hardware processing of the individual units without the interaction of the CA53.

RTC: Provides clocks for PWC

PWC: Generates timing for turning on the external power supply

CPG: Internal clock and reset control

Figure 9.1-1 Startup Sequence Outline

## 9.1.2 Boot Specifications

### 9.1.2.1 Overview

When this LSI is booted, the dual-core CA53 boots up and shifts core 1 to the WFI (wait for interrupt) state at the initial setting, and then it operates/controls with core 0 only. After the CA53 is started up, the program stored in the built-in ROM of the LSI (hereafter referred to as LSI\_InSW) operates, and the processing branches/executes according to the state of the MD6 pin. After the execution, if an error is detected, the MD8 pin is controlled to determine the cause of the error. The values of MD6-0 pins must be fixed before the reset (RSTN) is released.

**Figure 9.1-2** shows the boot sequence of this LSI.

This section describes the execution of the built-in ROM of the LSI (hereafter referred to as LSI\_InSW) shown in the figures.

Note 1. After the system operates on RAMA of the LSI, a transition to the destination for subsequent execution (RAMB of the LSI or DDR) is arbitrarily determined by the SystemFW processing (control over activation of each peripheral also follows the SystemFW).

Figure 9.1-2 Boot Sequence

### 9.1.2.2 Operation Specifications

In this section, execution of LSI\_InSW in **Figure 9.1-2** is described.

#### (1) Switching the Operation Specifications

The operating mode (normal, debug, forced write) and boot device (non-volatile memory mounted on the board) are selected by the state of the MD6-0 pins.

Note that the status of the MD6-0 pins is output to bits MD6-0 in the SYS\_MD\_MON register (00\_A3F0\_3100h).

##### a) Operation mode

Table 9.1-1 Selection of Operation Mode

| MD6 | Operation Mode    | Operation in Outline                                                                                                                                                                                                 |
|-----|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | Normal mode       | Mode which acquires the SystemFW stored in a non-volatile memory and executes it on RAMA (this mode is for use in normal activation).                                                                                |
| 1   | Forced write mode | Mode for writing the following file specified by the MD3 pin to a non-volatile memory. <ul style="list-style-type: none"> <li>SD: A file which is stored in the SD card via the SD interface of this LSI.</li> </ul> |

##### b) Boot device (non-volatile memory mounted on the board)

Table 9.1-2 Selection of Boot Device

| MD2                  | MD1 | MD0 | Boot Device        |
|----------------------|-----|-----|--------------------|
| 1                    | 1   | 0   | eMMC               |
| Other than the above |     |     | Setting prohibited |

#### (2) Operation when Normal Mode is Activated

Normal mode is the mode used for normal activation.

When LSI\_InSW is activated in normal mode, SystemFW\*<sup>1</sup> stored in the non-volatile memory is extended to RAMA. After checking that it has been extended normally, the control is transferred to the SystemFW extended on RAMA.

- The address where the SystemFW (including the boot loader) starts is 00\_0000\_0000h (the absolute address: 00\_8010\_0000h).

Write the SystemFW in that area beforehand.

**Note 1.** A 128-Kbyte firmware running on RAMA which performs expansion of the main SystemFW that is to run first following the system startup is defined as the boot loader.

### 9.1.2.3 Control Sequence in Each Operation Mode

This section describes the control sequence (flow of processing) in each operation mode.

In each mode, the following common processing is executed before the individual processing

#### NOTE

[FC-Bn] and [FC-B-Fm] at the end of the description of each processing in this section indicate the processing number of each flowchart in the figure below.

(n = 1 to 8, m = 1 to 5)

- **Figure 9.1-2, Boot Sequence**

#### ■ Common Processing

(a) The built-in ROM of the LSI is started up and initialization (CA53 initialization and initialization of other required hardware) is executed. [Fc-B1]

(b) Acquire the state of the MD6-0 pins from the MD6-0 bits of the SYS\_MD\_MON register. [Fc-B2]

Branch to a given operation mode by the value of MD6.

When MD6 = 0      ⇒ Move to normal mode.

When MD6 = 1      ⇒ Move to forced write mode.

## (1) Normal Mode

The following describes the flow of processing in normal mode.

### ■ Example of transition

- (c) Determine the non-volatile memory mounted on the board with the value of MD2-0 acquired in step (b) above. [Fc-B3]

Determine the non-volatile memory (type, voltage spec.) from the value of MD2-0 and execute the settings (pins, EMM, etc.) in the selected memory.

After that, acquire the ID information of the non-volatile memory and execute reading of the first data on the memory and determine whether acquisition of that value is possible or not (the acquired value itself is not determined at this time).

When acquisition is possible ⇒ Move to (d).

When acquisition is not possible ⇒ LED lighting (MD8) control: Proceed with error detection (Fc-B8) and end processing.

- (d) Acquire data in the specific area of eMMC via the EMM and determine whether the SystemFW\*<sup>1</sup> is or is not present. [Fc-B4]

When the acquired value is not 0000\_0000h ⇒ Move to (e): Proceed to the normal operation sequence.

When the acquired value is 0000\_0000h ⇒ Proceed to the load sequence.

- (e) Acquire the SystemFW (capacity: 125 Kbytes) from the start of the non-volatile memory and copy it to the start of RAMA. [Fc-B5]

- (f) Check the checksum information to confirm that the SystemFW has been normally transferred to RAMA. [Fc-B6]

Calculate the checksum for data which have been transferred to RAMA to compare whether it matches the checksum read from eMMC via the EMM.

When the result is a match ⇒ Move to (g).

When the result is a mismatch ⇒ LED lighting (MD8) control: Proceed with error detection (Fc-B8) and end processing.

- (g) Jump to the address where RAMA starts (00\_8010\_0000h). [Fc-B7]

~~ After the above steps, control of the user program (SystemFW)\*<sup>1</sup> is to proceed. ~~

**Note 1.** "SystemFW" defined here is assumed as a boot loader.

## (2) Forced Write Mode

The following describes the flow of processing in forced write mode.

This mode operates on the assumption that the SD card is connected to the SD interface (the SD card is inserted to the SD card connector).

The data specifications obtained with an other-party device (SD card) in the load sequence are as follows:

- Max. data capacity: 128 Kbytes
- Checksum value: 2 bytes (16 bits), little endian
- Address range: from 801F\_FFFEh to 801F\_FFFFh
- File name: B2\_INTSW.bin

### ■ Example of transition

- (c) Determine the non-volatile memory mounted on the board with the value of MD2-0 acquired in step (b) above. [Fc-B3"]

Determine non-volatile memory (type, voltage spec.) from the value of MD2-0 and execute the settings (pins, EMM, etc.) in the selected memory.

After that, acquire the ID information of the non-volatile memory and execute reading of the first data and determine whether acquisition of that value is possible or not (the acquired value itself is not determined at this time).

When acquisition is possible ⇒ Move to (d).

When acquisition is not possible ⇒ LED lighting (MD8) control: Proceed with error detection (Fc-B8) and end processing.

~~ After the above steps, the load sequence is to proceed. ~~

- (d) Access the SD card via SDIO, acquire the file format information, and transfer data (SystemFW) with the corresponding file name to RAMA. [Fc-B-F1]

When acquisition is possible ⇒ Move to (e).

When acquisition is not possible ⇒ LED lighting (MD8) control: Proceed with error detection (Fc-B8) and end processing.

- (e) Check the checksum information to confirm that the SystemFW has been normally transferred to RAMA. [Fc-B-F2]

Calculate the checksum value from the data which have been transferred to RAMA to compare whether it matches the expected value (the value stored within the SystemFW).

When the result is a match ⇒ Move to (f).

When the result is a mismatch ⇒ Proceed with LED lighting (MD8) control (Fc-B8) and end processing.

- (f) Control the unit that suits the non-volatile memory and erase the start area of that memory (the area to which the SystemFW is written). [Fc-B-F3]

- (g) Control the unit that suits the non-volatile memory and write the SystemFW stored in RAMA to the non-volatile memory. [Fc-B-F4]

- (h) Check the checksum information to confirm that the SystemFW has been normally transferred to the non-volatile memory. [Fc-B-F5]

Calculate the checksum value from the data which have been expanded in the non-volatile memory to compare whether it matches the expected checksum value acquired in step (e).

When the result is a match      ⇒ Proceed with LED lighting (MD8) control (Fc-B8) and end processing.

When the result is a mismatch ⇒ Proceed with LED lighting (MD8) control (Fc-B8) according to the detected error, and end processing.

#### 9.1.2.4 Error Detection and MD8 Pin Control

When an error in execution of LSI\_InSW is detected, the MD8 pin is controlled.

The detected error conditions and the MD8 pin control patterns for the errors are listed below.

By connecting an LED to this MD8 pin, whether the error has occurred can be judged by LED lighting. For the flow number, see **Figure 9.1-2**.

Table 9.1-3 List of Error Operation Modes

| Sequence              | Item      | Detected Error                                                                                                                                                                                                                                | Flow Number      | Control Pattern                    |
|-----------------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|------------------------------------|
| Normal operation/load | MD switch | MD0-2 = 111b                                                                                                                                                                                                                                  | Fc-B1            | Pattern1. Pin error                |
|                       | eMMC      | Failure in device ID acquisition*1                                                                                                                                                                                                            | Fc-B3, Fc-B3"    | Pattern2. Boot device error        |
|                       |           | Failure in reading of the first data*1                                                                                                                                                                                                        | Fc-B3, Fc-B3"    | Pattern2. Boot device error        |
|                       |           | Failure in checksum judgment<br>(The data stored in eMMC are expanded in RAMA, and the checksum value calculated from the expanded data and the expected value to be added to the last of the data are compared to check whether they match.) | Fc-B6            | Pattern3. LSI error                |

|                       |           | Failure in data writing*1                                                                                                                                                                                                                     | Fc-B-F4          | Pattern2. Boot device error        |
|                       |           | Failure in data reading*1                                                                                                                                                                                                                     | Fc-B-F5          | Pattern2. Boot device error        |
|                       |           |                                                                                                                                                                                                                                               |                  |                                    |

Note 1. A timeout of the execution command is detected, or an error is detected in the result of command execution.

Note 2. The SD interface is not connected, or an error is detected in the command response through the SD interface.

Figure 9.1-3 Control Patterns

### 9.1.2.5 Specifications of Register Settings

#### (1) Operating Clock Settings

The operating clocks to be set by LSI\_InSW are listed below.

Table 9.1-4 Operating Frequency Settings

| Category | Specified Clock            | Control Register |                |               | Frequency Setting (MHz)                         |
|----------|----------------------------|------------------|----------------|---------------|-------------------------------------------------|
|          |                            | Register Name    | Offset Address | Setting Value |                                                 |
| MAIN     | System clock               | CPG_SYS_DDIV     | 204h           | 0000_0001h    | ICB_ACLK: 200<br>GIC_CLK: 100<br>CPG_MPCLK: 200 |
|          | Source clock specification | CPG_CLK48_DSEL   | 214h           | 0000_0003h    | Specified by<br>CPG_CA53_DDIV                   |
|          | CA53 core clock            | CPG_CA53_DDIV    | 200h           | 0000_0003h    | 249                                             |
| eMMC, SD | Main clock                 | CPG_SDIEMM_SSEL  | 300h           | 0000_0001h    | 200                                             |
|          | SD clock (SDCLK)           | SD_CLK_CTRL      | 90h            | 0000_0104h    | 12.5                                            |

#### (2) Initial Settings

The settings for register processing in LSI\_InSW are listed below. [Fc-B1]

Table 9.1-5 Initial Settings (RAMA)

| Unit | Register Name | Address       | Setting Value | Setting in Outline                                                                               |
|------|---------------|---------------|---------------|--------------------------------------------------------------------------------------------------|
| RAMA | RAMA_ECC_CNT  | 00_A3F0_3110h | 0000_0001h    | Enable RAMA ECC.                                                                                 |
|      | RAMA_INIT     | 00_A3F0_3114h | 0000_0001h    | Change the enabled setting for initialization of the RAMA ECC code area to the disabled setting. |
|      | W0_EC710CTL   | 00_92F4_0000h | 0000_4050h    | Set the recommended value in the ECC control register.                                           |
|      | W1_EC710CTL   | 00_92F4_0040h | 0000_4050h    | Set the recommended value in the ECC control register.                                           |
|      | W2_EC710CTL   | 00_92F4_0080h | 0000_4050h    | Set the recommended value in the ECC control register.                                           |
|      | W3_EC710CTL   | 00_92F4_00C0h | 0000_4050h    | Set the recommended value in the ECC control register.                                           |

### 9.1.2.6 Supplementary Notes on Specifications

The specifications of LSI\_InSW operations are as follows.

#### (a) Bootloader area (information of allocation on RAMA)

| Item                 | Address (Range)          | Size              |
|----------------------|--------------------------|-------------------|
| Bootloader body      | 8010_0000h to 8011_FFF7h | 128 Kbytes        |
| Bootloader body size | 801F_FFF8h to 801F_FFFDh | 4 bytes           |
| Checksum value       | 801F_FFFEh to 801F_FFFFh | 2 bytes (16 bits) |

#### (b) Checksum calculation specifications

- Addition width: 16 bits
- Bit width for comparison after addition: 16 bits
- Addition in little-endian representation

#### (c) Judging the validity of non-volatile memory

The target non-volatile memory is judged as a usable device when the device ID and the data at the start address can be obtained (i.e., judged when a command response can be executed without an error, instead of judging the obtained value).

#### (d) Supplementary notes on the specifications of the load sequence

- When using this mode, be sure to insert an SD card into the SD card connector before supplying power to the board on which this LSI is mounted.
- The write file to be stored in the SD card must meet the following specifications.

| Item               | Description                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| File name          | B2_INTSW                                                                                                                                                                                                                                                                                                                                                                                              |
| Format             | One partition, FAT32 (SD-HC)                                                                                                                                                                                                                                                                                                                                                                          |
| Supplementary note | <ul style="list-style-type: none"> <li>• Only one target write file name must exist.</li> <li>• Files other than the target one can be stored up to ten files in the same partition.</li> <li>• Size judgement on the target write file name is not performed in the on-chip ROM.<br/>Detection of errors in the target write file is performed by using the checksum calculation results.</li> </ul> |

#### (e) Specifications of load sequence erase processing

- Range of erasure  
eMMC: Erase the boot partition.
- If a problem occurs during the load sequence, erase processing, etc. is not performed on the non-volatile memory (eMMC).

### 9.1.3 CA53 Core1 Startup Setting

The following describes the startup procedure of CA53 core 1 following the bootloader after executing LSI\_InSW.

#### [Startup control method]

- (1) Specification of the storage address of the software to be executed by CA53 core 1

CA53\_RVA1CRL register (A3F0\_0028h), CA53\_RVA1CRH register (A3F0\_002Ch)

- (2) Deployment of the software to be executed by CA53 core 1

Deployment of the software to the area (memory: RAMA/B, LPDDR4) specified in (1)

- (3) Reset execution

CPG\_RST8 register (A350\_061Ch): UNIT3\_RSTB bit = 0b, UNIT1\_RSTB bit = 0b

- (4) Wakeup

CA53\_PSCR register (A3F0\_003Ch): CA53\_DBGPWRDUP[1] bit = 1b

- (5) Reset release

CPG\_RST8 register (A350\_061Ch): UNIT3\_RSTB bit = 1b, UNIT1\_RSTB bit = 1b

### 9.1.4 Power Off Processing

While the internal power supply state is the system-on state, the external power supply turn-off sequence is activated by setting the PWC registers and the system shifts to the off state.

## 9.2 Power Management

This section describes the power management function of this LSI.

This LSI is equipped with the following power management functions to achieve low power consumption.

- Clock stop control
- Power switch control

### 9.2.1 Clock Stop Control

This function reduces the operating power by stopping the clock of units that do not need to operate as a system.

The desired clock can be stopped by setting the CPG clock ON/OFF control register CPG (CPG\_CLK\_ON1 to CPG\_CLK\_ON27). For details, see the CPG section.

### 9.2.2 Power Switch Control

This function reduces the leakage power by turning off the power of power domains that do not need to be operate as a system.

By setting the PMC power supply enable register (PMC: PMC\_SPLY\_ENA), the power supplied to the power supply domains of PD\_MEM, PD\_VIDEO0, PD\_VIDEO1, PD\_RFX, PD\_DRPA, and PD\_CA53 can be turned off. For details, see the PMC section.

## Section 10 CPU

This section describes the functions of the Cortex-A53 subsystem (CA53).

### 10.1 Functional Overview

The CA53 is a subsystem with an Arm® Cortex®-A53 processor (r0p4). For details on the Cortex-A53, see *the ARM Cortex-A53 MPCore Processor Technical Reference Manual* and *the ARM Cortex-A53 MPCore Processor Advanced SIMD and Floating-point Extension Technical Reference Manual*.

In this section, the subsystems will be referred to as “CA53”, Arm’s CPU (hierarchy including SCU) as “Cortex-A53”, and Cortex-A53’s internal processing-elements as “Core”. If these are not specified, the subsystem is indicated.

#### 10.1.1 CA53 Subsystem Functions

**Table 10.1-1** lists the subsystem functions.

Table 10.1-1 Subsystem Functions

| Item              | Function                                                                                                           |
|-------------------|--------------------------------------------------------------------------------------------------------------------|
| Equipped CPU      | Cortex-A53 r0p4 (ARMv8-A)<br>Number of cores installed: 2<br>L1\$(I/D) = 32 Kbytes/ 32 Kbytes<br>L2\$ = 512 Kbytes |
| Internal register | Status monitoring of Cortex-A53                                                                                    |

### 10.1.2 Cortex-A53 Configuration

**Table 10.1-2** lists the configuration (embedded specification) of the Cortex-A53.

Table 10.1-2 Cortex-A53 Configuration

| Item                                         | Setting               |
|----------------------------------------------|-----------------------|
| Number of Cortex A53 cores                   | 2                     |
| Arm® Neon™/FPU Engine                        | Available             |
| Cryptography Engine                          | Not available         |
| L1 cache size (instruction)                  | 32 Kbytes             |
| L1 cache size (data)                         | 32 Kbytes             |
| ECC for the L1 cache                         | Available             |
| L2 cache                                     | Available             |
| L2 cache size                                | 512 Kbytes            |
| ECC for the L2 cache                         | Available             |
| Setting the data input latency for L2 cache  | 1 cycle               |
| Setting the data output latency for L2 cache | 2 cycles              |
| Architecture execution mode                  | 64-bit mode (AArch64) |
| Byte order                                   | Little endian         |
| Core 0 reset vector position                 | 00_8000_0000h         |
| Core 1 reset vector position                 | 00_8000_0000h         |

## 10.2 Register Description

This section describes the registers that have been added as the Cortex-A53 subsystem. For details on the Cortex-A53 registers, see *the ARM Cortex-A53 MPCore Processor Technical Reference Manual* and *the ARM Cortex-A53 MPCore Processor Advanced SIMD and Floating-point Extension Technical Reference Manual*.

For the base address of the registers (<CA53\_S0\_base>), see “Address Map Details” in the Address Map section.

### 10.2.1 List of Registers

**Table 10.2-1** is a list of registers.

Table 10.2-1 List of Registers

| Offset Address                  | Register Name                                            | Abbreviation | Initial Value | Access Unit (bits)*1 |
|---------------------------------|----------------------------------------------------------|--------------|---------------|----------------------|
| Cortex-A53 pin control register |                                                          |              |               |                      |
| 000h to 024h                    | Reserved                                                 | —            | —             | —                    |
| 028h                            | CA53 Core1 Reset Vector Address Configuration Register L | CA53_RVA1CRL | 8000_0000h    | 32 bits              |
| 02Ch                            | CA53 Core1 Reset Vector Address Configuration Register H | CA53_RVA1CRH | 0000_0000h    | 32 bits              |
| 030h to 038h                    | Reserved                                                 | —            | —             | —                    |
| 03Ch                            | CA53 Processor Power Status Configuration Register       | CA53_PSCR    | 0000_0003h    | 32 bits              |
| 040h to 3FCh                    | Reserved                                                 | —            | —             | —                    |
| Cortex-A53 monitor register     |                                                          |              |               |                      |
| 400h                            | CA53 Warm Reset Request Monitor Register                 | CA53_WRIRMR  | 0000_000xh*2  | 32 bits              |
| 404h to 40Ch                    | Reserved                                                 | —            | —             | —                    |
| 410h                            | CA53 L2cache Hardware Flush Complete Monitor Register    | CA53_L2HFMR  | 0000_000xh*2  | 32 bits              |
| 414h                            | CA53 CPUECTLR.SMPEN Bit Monitor Register                 | CA53_SMPENMR | 0000_000xh*2  | 32 bits              |
| 418h to FFCh                    | Reserved                                                 | —            | —             | —                    |

Note 1. Access other than 32 bits and access to the reserved registers are prohibited. The operation is not guaranteed if accessed.

Note 2. x is undefined.

10.2.2 Register Descriptions

10.2.2.1 CA53 Core1 Reset Vector Address Configuration Register L (CA53\_RVA1CRL)

This register sets the lower-order side [31:2] of the reset vector base address in the AArch64 state of core 1.

This register setting is sampled while each processor power-up reset or each core reset is asserted.

Access Size: 32 bits  
Address(es): <CA53\_S0\_base> + 0028h  
Initial Value: 8000\_0000h

Table 10.2-2 CA53\_RVA1CRL Register Contents

| Bit Position | Bit Name              | Description                                                               |
|--------------|-----------------------|---------------------------------------------------------------------------|
| 31 to 2      | CA53_RVBARADDR1[31:2] | Set the reset vector base address [31:2] in the AArch64 state of core 1.  |
| 1, 0         | —                     | Reserved. These bits are read as 0b. The write value should always be 0b. |

10.2.2.2 CA53 Core1 Reset Vector Address Configuration Register H (CA53\_RVA1CRH)

This register sets the higher-order side [39:32] of the reset vector base address in the AArch64 state of core 1.

This register setting is sampled while each processor power-up reset or each core reset is asserted.

Access Size: 32 bits  
Address(es): <CA53\_S0\_base> + 002Ch  
Initial Value: 0000\_0000h

|               |    |    |    |    |    |    |    |    |                        |    |    |    |    |    |    |    |

Table 10.2-3 CA53\_RVA1CRH Register Contents

| Bit Position | Bit Name               | Description                                                               |
|--------------|------------------------|---------------------------------------------------------------------------|
| 31 to 8      | —                      | Reserved. These bits are read as 0b. The write value should always be 0b. |
| 7 to 0       | CA53_RVBARADDR1[39:32] | Set the reset vector base address [39:32] in the AArch64 state of core 1. |

10.2.2.3 CA53 Processor Power Status Configuration Register (CA53\_PSCR)

This register is used to set the power status of each core.

Access Size: 32 bits  
Address(es): <CA53\_S0\_base> + 003Ch  
Initial Value: 0000\_0003h

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |                         |    |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------------------------|----|
| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17                      | 16 |

### 10.3 Functional Description

For details on the Cortex-A53 functions, see *the ARM Cortex-A53 MPCore Processor Technical Reference Manual* and *the ARM Cortex-A53 MPCore Processor Advanced SIMD and Floating-point Extension Technical Reference Manual*.

### 10.4 Operating Procedure

For details on the operating procedures of the Cortex-A53, see *the ARM Cortex-A53 MPCore Processor Technical Reference Manual* and *the ARM Cortex-A53 MPCore Processor Advanced SIMD and Floating-point Extension Technical Reference Manual*.

# Section 11 System Counter (SYC)

This section describes the functions of the system counter (SYC).

The SYC is the unit used to generate the count values used by the generic timer in the CA53. It uses a timestamp generator, one of the components of the Arm® CoreSight™ SoC-400, to generate a 64-bit count value. For details on the timestamp generator, see *the ARM CoreSight SoC-400 Technical Reference Manual*.

## 11.1 Functional Overview

Table 11.1-1 is an overview of functions.

Table 11.1-1 Overview of Functions

| Item                | Function                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Equipped functions  | <ul style="list-style-type: none"><li>Generates 64-bit gray code count values<ul style="list-style-type: none"><li>Convert the value generated by the timestamp generator to gray code and output it.</li></ul></li><li>Halt-on-debug function<ul style="list-style-type: none"><li>Halt/resume of the count value in debug mode is possible according to the request from CST.</li></ul></li></ul> |
| Operating frequency | 24 MHz                                                                                                                                                                                                                                                                                                                                                                                              |

## 11.2 Block Diagram

Figure 11.2-1 shows a block diagram of the SYC.

Figure 11.2-1 Block Diagram

## 11.3 Address Space

**Table 11.3-1** lists the APB address space (SYC\_S0\_base). The SYC has an APB address space of 8 Kbytes.

For details on the APB address space (SYC\_S0\_base), see “Address Map Details” in the Address Map section.

Table 11.3-1 Address Space (SYC\_S0)

| Offset Address | Access Target                                          |
|----------------|--------------------------------------------------------|
| 0000h to 0FFFh | PSELCTRL region & PSELCTRL region Management registers |
| 1000h to 1FFFh | PSELREAD region & PSELREAD region Management registers |

## 11.4 Register Description

For details on respective registers, see *the ARM CoreSight SoC-400 Technical Reference Manual 3.10 Timestamp generator*.

## 11.5 Functional Description

Access control is performed from one APB interface of this unit to two APB interfaces of the timestamp generator. The access to the first 4 Kbytes of the 8-Kbyte address area of the SYC is controlled to the PSELCTRL area, while the access to the second 4 Kbytes is controlled to the PSELREAD area. Only the secure access to the PSELCTRL area is allowed. In case of non-secure access, a slave error response is made.

### 11.5.1 Halt-on-Debug Function

This unit supports the halt-on-debug function of the timestamp generator.

# Section 12 RAM A (RAMA)

This section describes functions of the RAM A (RAMA).

## 12.1 Functional Overview

This unit is a RAM with ECC error detection and correction functions. This unit has a function to detect and correct errors by ECC of data recorded in the internal RAM. It also has a FIFO function that retains transactions when accesses from various channels to the RAM are in conflict and access is not possible.

**Figure 12.1-1** shows the connection diagram of the RAMA.

Figure 12.1-1 Connection Diagram

## 12.2 Pin Functions

### 12.2.1 List of Internal Pins

**Table 12.2-1** lists the internal pins.

Table 12.2-1 List of Internal Pins

| Pin name    | I/O    | Function                                                                |
|-------------|--------|-------------------------------------------------------------------------|
| RAM Access  |        |                                                                         |
| VECCEN      | Input  | Pin for switching enabling and disabling of error correction by the ECC |
| ECC Control |        |                                                                         |
| RAM_INIT    | Input  | Controlling initialization of the RAM ECC code area                     |
| RAM_INITEND | Output | Ending initialization of the RAM ECC code area                          |

The following describes the internal pin functions of the RAMA unit.

#### 12.2.1.1 RAM Access

The pin of this category is mainly for controlling the method for RAM access and the restrictions on access.

##### VECCEN (Input)

This pin is for switching enabling and disabling of error correction by the ECC. The ECC is enabled when the pin is fixed to the high level and disabled when it is fixed to the low level. For details of the functions of this pin, see **Section 12.5.1.2, VECCEN Pin Functions**. Note that this signal is synchronized through a two-2-FF synchronizer with which it goes to the high level at the time of a reset.

#### 12.2.1.2 ECC Control

The pins of this category are related to the ECC macro and ECC control. Three interrupt outputs are the signals bundled with multiple interrupt output signals of the ECC macro. For details of the connection, see **Section 12.5.1.4, Error Detection and Correction Function**.

##### RAM\_INIT (Input), RAM\_INITEND (Output)

When RAM\_INIT is changed from the low to the high level and the clock is input, RAM\_INITEND changes from the low to the high level after certain clock cycles, and the internal RAM data and the whole area of the ECC code are initialized.

12.3 Address Space

This unit has a retention RAM area and a register area separately.

**Figure 12.3-1** shows the retention RAM area. **Figure 12.3-2** shows the register area.

For the base address of the register (<RAMA\_S1\_base>), see “Address Map Details” in the Address Map section.

Figure 12.3-1 Memory Map of RAM

Figure 12.3-2 Memory Map of Register

## 12.4 Register Description

For the base address of the register (<RAMA\_S1\_base>), see the Address Map section.

### 12.4.1 List of Registers

**Table 12.4-1** is the list of registers.

Table 12.4-1 List of Registers (1/2)

| Offset Address | Register Name                              | Abbreviation       | Initial Value | Access Unit (bits) |
|----------------|--------------------------------------------|--------------------|---------------|--------------------|
| <b>ECC_W0</b>  |                                            |                    |               |                    |
| 00h            | ECC Control Register                       | RAMA_Wm_EC710C TL  | 0000_001xh*1  | 32                 |
| 04h to 0Ch     | Reserved (When reading, 0 is always read.) | —                  | 0000_0000h    | 32                 |
| 10h            | ECC Error Address Register 0               | RAMA_Wm_EC710E AD0 | 0000_0000h    | 32                 |
| 14h            | ECC Error Address Register 1               | RAMA_Wm_EC710E AD1 | 0000_0000h    | 32                 |
| 18h            | ECC Error Address Register 2               | RAMA_Wm_EC710E AD2 | 0000_0000h    | 32                 |
| 1Ch            | ECC Error Address Register 3               | RAMA_Wm_EC710E AD3 | 0000_0000h    | 32                 |
| 20h            | ECC Error Address Register 4               | RAMA_Wm_EC710E AD4 | 0000_0000h    | 32                 |
| 24h            | ECC Error Address Register 5               | RAMA_Wm_EC710E AD5 | 0000_0000h    | 32                 |
| 28h            | ECC Error Address Register 6               | RAMA_Wm_EC710E AD6 | 0000_0000h    | 32                 |
| 2Ch            | ECC Error Address Register 7               | RAMA_Wm_EC710E AD7 | 0000_0000h    | 32                 |
| 30h to 3Ch     | Reserved (When reading, 0 is always read.) | —                  | 0000_0000h    | 32                 |
| <b>ECC_W1</b>  |                                            |                    |               |                    |
| 40h            | ECC Control Register                       | RAMA_Wm_EC710C TL  | 0000_001xh*1  | 32                 |

Note 1. Bit 0 is undefined.

## 12.4.2 Register Descriptions

The function description of each register is given below.

### 12.4.2.1 ECC Control Register (RAMA\_Wm\_EC710CTL) (m = 0 to 3)

This register controls the status and mode of the ECC macro.

*Note:* Write to the control bits (bits 7 to 3) of this register when AXI access is not performed.

**Access Size:** 32 bits

**Address(es):** <RAMA\_S1\_base> + 0000h  
<RAMA\_S1\_base> + 0040h  
<RAMA\_S1\_base> + 0080h  
<RAMA\_S1\_base> + 00C0h

**Initial Value:** 0000\_001xh

| Bit           | 31        | 30      | 29      | 28      | 27      | 26      | 25      | 24      | 23      | 22      | 21      | 20      | 19      | 18      | 17      | 16      |

Table 12.4-2 RAMA\_Wm\_EC710CTL Register Contents (1/2)

| Bit Position | Bit Name                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 16     | ECDEDF[7:0]<br>ECSEDF[7:0] | ECDEDF[7:0]: 2-bit error detection flag<br>ECSEDF[7:0]: 1-bit error detection flag<br>This bit is a flag indicating an error if stored in the error address register when error detection is enabled. 1b is set to ECSEDF[7:0] for a 1-bit error and to ECDEDF[7:0] for a 2-bit error. Since this bit is read-only, writing a value does not reflect it. This bit is cleared by writing 1b to ECER2C and ECER1C of bits 10 and 9, respectively.                    |
| 15, 14       | EMCA[1:0]                  | Access control bit to ECC mode selection bit<br>These bits are the write trigger bits for bits 7 and 6 and the value of these bits is always 0b at normal times. Writing 01b to these bits enables write to bits 7 and 6.                                                                                                                                                                                                                                          |
| 13, 12       | —                          | Reserved. The write value should be always 0b.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 11           | ECOVFF                     | ECC overflow detection flag<br>If a new error address is detected with all error address registers holding an error address, this bit sets a flag and an overflow interrupt is output. This bit is read-only and should be cleared with bits 10 and 9.<br>0b: No overflow has occurred after resetting or after clearing this bit by bits 10 and 9.<br>1b: Indicates that the error address register has overflowed.                                               |
| 10           | ECER2C                     | 2-bit ECC error detection flag clear bit<br>The read value is always 0, and the 2-bit error flag bit ECER2F is cleared by writing 1b. The overflow detection flag ECOVFF, ECC 2-bit error detection flag ECDEDF[7:0], and ECC 1-bit error detection flag ECSEDF[7:0] are also cleared. Clearing this bit has priority in the case of a conflict with the 2-bit ECC error detection flag factor. The internal state does not change when 0b is written to this bit. |

| 13 to 0      | ECEAD0[13:0] | ECC error address register<br>This is a read-only register that captures the RAM address using the detection signal as a trigger and stores it as the ECC error occurrence address from the ECEADn=0th position when an ECC error is detected with error judgment enabled.<br>The bit width of this register changes depending on the RAM mounting area. The read value is always 0b for the other bits. This address register is cleared to 0b together with the flag by clearing the status flag of ECE R2F or ECE R1F. |

#### NOTE

##### • Correspondence between AXI address and ECEAD address

The address stored is a RAM address and is stored as a 128-bit aligned address, it is different from an AXI address that is byte aligned (8 bits). The correspondence between the two is as follows.

The address stored in ECEAD = AXI address >> 4 (4-bit shift right)

- The address indicated by the register of ECC W0 indicates that there was an error in data [31:0] in the corresponding address area of RAM.
- The address indicated by the register of ECC W1 indicates that there was an error in data [63:32] in the corresponding address area of RAM.
- The address indicated by the register of ECC W2 indicates that there was an error in data [95:64] in the corresponding address area of RAM.
- The address indicated by the register of ECC W3 indicates that there was an error in data [127:96] in the corresponding address area of RAM.

For details on AXI addresses and register areas, see the Address Space section.

### 12.4.2.3 ECC Error Address Register 1 (RAMA\_Wm\_EC710EAD1) (m = 3 to 0)

This register is a read-only register that holds the ECC error occurrence address.

**Access Size:** 32 bits

**Address(es):** <RAMA\_S1\_base> + 0014h  
 <RAMA\_S1\_base> + 0054h  
 <RAMA\_S1\_base> + 0094h  
 <RAMA\_S1\_base> + 00D4h

**Initial Value:** 0000\_0000h

| 31 to 14     | —            | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 13 to 0      | ECEAD2[13:0] | <p>ECC error address register</p> <p>This is a read-only register that captures the RAM address using the detection signal as a trigger and stores it as the ECC error occurrence address from the ECEADn=0th position when an ECC error is detected with error judgment enabled.</p> <p>The bit width of this register changes depending on the RAM mounting area. The read value is always 0b for the other bits. This address register is cleared to 0b together with the flag by clearing the status flag of ECE R2F or ECE R1F.</p> |

#### NOTE

##### • Correspondence between AXI address and ECEAD address

The address stored is a RAM address and is stored as a 128-bit aligned address, it is different from an AXI address that is byte aligned (8 bits). The correspondence between the two is as follows.

The address stored in ECEAD = AXI address >> 4 (4-bit shift right)

- The address indicated by the register of ECC W0 indicates that there was an error in data [31:0] in the corresponding address area of RAM.
- The address indicated by the register of ECC W1 indicates that there was an error in data [63:32] in the corresponding address area of RAM.
- The address indicated by the register of ECC W2 indicates that there was an error in data [95:64] in the corresponding address area of RAM.
- The address indicated by the register of ECC W3 indicates that there was an error in data [127:96] in the corresponding address area of RAM

For details on AXI addresses and register areas, see the Address Space section.

### 12.4.2.5 ECC Error Address Register 3 (RAMA\_Wm\_EC710EAD3) (m = 3 to 0)

This register is a read-only register that holds the ECC error occurrence address.

**Access Size:** 32 bits

**Address(es):** <RAMA\_S1\_base> + 001Ch  
 <RAMA\_S1\_base> + 005Ch  
 <RAMA\_S1\_base> + 009Ch  
 <RAMA\_S1\_base> + 00DCh

**Initial Value:** 0000\_0000h

#### NOTE

##### • Correspondence between AXI address and ECEAD address

The address stored is a RAM address and is stored as a 128-bit aligned address, it is different from an AXI address that is byte aligned (8 bits). The correspondence between the two is as follows.

The address stored in ECEAD = AXI address >> 4 (4-bit shift right)

- The address indicated by the register of ECC W0 indicates that there was an error in data [31:0] in the corresponding address area of RAM.
- The address indicated by the register of ECC W1 indicates that there was an error in data [63:32] in the corresponding address area of RAM.
- The address indicated by the register of ECC W2 indicates that there was an error in data [95:64] in the corresponding address area of RAM.
- The address indicated by the register of ECC W3 indicates that there was an error in data [127:96] in the corresponding address area of RAM.

For details on AXI addresses and register areas, see the Address Space section.

### 12.4.2.7 ECC Error Address Register 5 (RAMA\_Wm\_EC710EAD5) (m = 3 to 0)

This register is a read-only register that holds the ECC error occurrence address.

**Access Size:** 32 bits

**Address(es):** <RAMA\_S1\_base> + 0024h  
 <RAMA\_S1\_base> + 0064h  
 <RAMA\_S1\_base> + 00A4h  
 <RAMA\_S1\_base> + 00E4h

**Initial Value:** 0000\_0000h

| 31 to 14     | —            | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 13 to 0      | ECEAD5[13:0] | <p>ECC error address register</p> <p>This is a read-only register that captures the RAM address using the detection signal as a trigger and stores it as the ECC error occurrence address from the ECEADn=0th position when an ECC error is detected with error judgment enabled.</p> <p>The bit width of this register changes depending on the RAM mounting area. The read value is always 0b for the other bits. This address register is cleared to 0b together with the flag by clearing the status flag of ECE R2F or ECE R1F.</p> |

#### NOTE

##### • Correspondence between AXI address and ECEAD address

The address stored is a RAM address and is stored as a 128-bit aligned address, it is different from an AXI address that is byte aligned (8 bits). The correspondence between the two is as follows.

The address stored in ECEAD = AXI address >> 4 (4-bit shift right)

- The address indicated by the register of ECC W0 indicates that there was an error in data [31:0] in the corresponding address area of RAM.
- The address indicated by the register of ECC W1 indicates that there was an error in data [63:32] in the corresponding address area of RAM.
- The address indicated by the register of ECC W2 indicates that there was an error in data [95:64] in the corresponding address area of RAM.
- The address indicated by the register of ECC W3 indicates that there was an error in data [127:96] in the corresponding address area of RAM.

For details on AXI addresses and register areas, see the Address Space section.

### 12.4.2.8 ECC Error Address Register 6 (RAMA\_Wm\_EC710EAD6) (m = 3 to 0)

This register is a read-only register that holds the ECC error occurrence address.

**Access Size:** 32 bits

**Address(es):** <RAMA\_S1\_base> + 0028h  
 <RAMA\_S1\_base> + 0068h  
 <RAMA\_S1\_base> + 00A8h  
 <RAMA\_S1\_base> + 00E8h

**Initial Value:** 0000\_0000h

#### NOTE

##### • Correspondence between AXI address and ECEAD address

The address stored is a RAM address and is stored as a 128-bit aligned address, it is different from an AXI address that is byte aligned (8 bits). The correspondence between the two is as follows.

The address stored in ECEAD = AXI address >> 4 (4-bit shift right)

- The address indicated by the register of ECC W0 indicates that there was an error in data [31:0] in the corresponding address area of RAM.
- The address indicated by the register of ECC W1 indicates that there was an error in data [63:32] in the corresponding address area of RAM.
- The address indicated by the register of ECC W2 indicates that there was an error in data [95:64] in the corresponding address area of RAM.
- The address indicated by the register of ECC W3 indicates that there was an error in data [127:96] in the corresponding address area of RAM.

For details on AXI addresses and register areas, see the Address Space section.

## 12.5 Functional Description

In subsequent sections, the register name prefix (RAMA\_) is omitted.

### 12.5.1 ECC Control Function

#### 12.5.1.1 ECC Macro

This unit generates 7-bit ECC code for 32-bit data during encoding, and can detect and correct errors by inputting these data and ECC data during decoding.

For this unit, error detection and correction is performed for 128-bit data by generating 7-bit ECC codes using ECC macros for every 32 bits, for a total of 28 bits. The ECC macro function can store up to eight addresses where errors have occurred in registers, which can be read from the APB. Various interrupts (1-bit error detection, 2-bit error detection, and error address overflow) can be generated at this time.

#### 12.5.1.2 VECEN Pin Functions

The operations are as follows when VECEN = 1.

- Controls so that the ECC code is written to the redundant bit RAM.
- Control by the ECC control circuit is applied to perform read-modify-write operation at the time of partial writing other than 32-, 64-, 96-, or 128-bit access.

The operations are as follows when VECEN = 0.

- Controls so that the ECC code is not written to the redundant bit RAM.
- The results of ECC calculation are not reflected in input/output data.

Note that, if error detection of the ECC macro and interrupt output are enabled, an unintended interrupt may occur, so be sure to set masking.

#### 12.5.1.3 Procedure for Switching VECEN

For the flow of switching VECEN, see **Section 12.5.2, Initialization Flow**.

### 12.5.1.4 Error Detection and Correction Function

#### (1) ECC Error Correction and Detection Function

The following functions are realized by the ECC macro in this unit. The following functions can be controlled by the registers in the ECC macro.

- Encoding of ECC codes for data stored in RAM
- Decoding from data stored in RAM and ECC code
- 1-bit error correction by the above decoding
- 2-bit error detection by the above decoding
- Interrupt control and flag retention for 1-bit error correction and 2-bit error detection

The error judgment and overflow interrupt output from this unit is connected to the internal ECC macro as shown below, and is output one clk later than the ECC macro interrupt output.

Figure 12.5-1 Connection between ECC Macro Interrupt Output and Macro Interrupt

### 12.5.1.5 ECC Error Address Retention and Address Register Overflow

#### (1) ECC Error Address Retention Register

The ECC macro in this unit has a function to capture addresses by triggering an error detection. The captured address is stored in the error address register in the ECC macro, and eight such address registers are included. Each time a different address or error factor occurs, the address at that time is stored in the error address register in the next stage. The flag indicating the error factor of the captured address is held in the upper 16 bits of the EC710CTL register.

When a 2-bit ECC error or 1-bit ECC error is detected with ECC error judgment enabled, the detection signal is used as a trigger to capture the address of the factor and hold it in the error address register (Wx\_EC710EADn). In this case, set the ECDEDFm and ECSEDFm of the upper 16 bits of the Wx\_EC710CTL register to indicate the applicable error. "m" in ECDEDFm and ECSEDFm refers to Wx\_EC710EADn.

*(Example)*

If the error that occurred at the address stored in the error address register Wx\_EC710EAD2 is a 2-bit error, ECDEDF2 is set to 1; if it is a 1-bit error, ECSEDF2 is set to 1.

#### (2) Address Holding Register Overflow

An interrupt is output when a new error address is detected while the error address has already been stored in all the error address holding registers. (A new error address here refers to an address other than the one stored in the error address register, or an error address with a different error factor in an already stored address.)

#### CAUTION

Normally, the error address will not be overwritten by the error address when the error address register overflows. Only when a 2-bit error occurs with all 8 registers filled with 1-bit error addresses (when the error address register detection flags are all 1-bit errors), ECC error address register 7 will be overwritten with the overflowed 2-bit error address. At this time, if 2-bit error interrupt is enabled, 2-bit error interrupt and overflow interrupt will be output. If 2-bit error interrupt is disabled, only overflow interrupt will be output.

12.5.1.6 Interrupt Processing Flow

The following are two examples of the processing flow after various error interruptions.

(1) Flow for Processing Every Error Interrupt

In this flow, all error interrupts are unmasked, and processing is performed for every error that occurs. Stop AXI access before starting the flow.

Figure 12.5-2 Flow for Processing Every Error Interrupt (Release All Interrupt Masks)

## (2) Flow for Processing 2-bit Error and Overflow Interrupt

This flow assumes that 1-bit errors will be corrected, and that 1-bit error interrupts will be masked, and 2-bit errors and overflows will be handled. As in the flow described in **Section 12.5.1.6(1), Flow for Processing Every Error Interrupt**, stop AXI access before starting the flow.

Figure 12.5-3 Flow to be Processed at 2-bit Error and Overflow Interrupt (1-bit Error Interrupt Masked)

## 12.5.2 Initialization Flow

The procedure for initializing the unit is shown below. When initializing, stop normal access from AXI and reset the unit before doing so.

The initialization flow is shown below. There are two different flows depending on whether the RAM is initialized by S/W or H/W.

In this product, VECCEN, RAM\_INIT, and RAM\_INITEND are connected to the SYS unit and have control/monitoring registers (SYS\_RAM\_A\_ECC\_CNT, SYS\_RAM\_A\_INIT, SYS\_RAM\_A\_INIT\_END) for the corresponding signals.

### 12.5.2.1 When Initializing RAM with S/W

Figure 12.5-4 Initialization Flow by S/W

### 12.5.2.2 When Initializing RAM with H/W

Figure 12.5-5 Initialization Flow by H/W

## 12.6 Usage Notes

### 12.6.1 Priority for Simultaneous Write and Read Access

Since AXI has separate write and read channels, it may receive write and read requests at the same time. The priority of simultaneous requests is as follows.

- When there is no access, Read has priority.
- If simultaneous accesses occur after a Read access, Write has priority.
- When simultaneous accesses occur after a Read access, Read has priority.

If it continues to accept requests at the same time, Write and Read will be processed alternately after Read is executed. Therefore, if Read and Write are performed to the same address at the same time, the order in which they are reflected in RAM will change with each access. To keep the order of Write and Read accesses to the same address, wait for one of the Read or Write cycles to finish on the master side before generating the other cycle.

### 12.6.2 Exclusive Access

When an exclusive read is performed for the same access information with different AxIDs (AXI bus IDs), the portion of the exclusive read that can be monitored succeeds, and the AxID and address information are monitored separately. After this, when an exclusive write is performed, the exclusive access succeeds only for the first exclusive write that has occurred, and the exclusive access monitor for the same AxID, including its own and others, which was set in the same access information, is cleared, and subsequent exclusive writes fail.

### 12.6.3 ECC Error Address Retention and Address Register Overflow

Normally, the error address will not be overwritten by the error address when the error address register overflows. Only when a 2-bit error occurs with all 8 registers filled with 1-bit error addresses (when the error address register detection flags are all 1-bit errors), ECC error address register 7 will be overwritten with the overflowed 2-bit error address. At this time, if 2-bit error interrupt is enabled, 2-bit error interrupt and overflow interrupt will be output. If 2-bit error interrupt is disabled, only overflow interrupt will be output.

## Section 13 RAM B (RAMB)

This section describes the functions of RAM B (RAMB).

### 13.1 Functional Overview

The RAMB is mainly used by the CA53 for boot and work areas.

The RAMB has a capacity of 1 MB and consists of four 256-KB SRAMs.

**Figure 13.1-1** shows the connection diagram of the RAMB.

Figure 13.1-1 Schematic of RAMB Connection

### 13.2 Address Space

For the RAMB address allocation details, see “Address Map Details” in the Address Map section.

## Section 14 ROM

This section describes the functions of the ROM.

### 14.1 Functional Overview

This ROM is a boot ROM, which stores the boot F/W for CA53 (LSI\_InSW).

The ROM has a capacity of 128 KB.

**Figure 14.1-1** shows the connection diagram of the ROM.

Figure 14.1-1 Schematic of ROM Connection

### 14.2 Address Space

For the ROM address allocation details, see “Address Map Details” in the Address Map section.

## Section 15 Watchdog Timer (WDT)

This section describes the functions of the watchdog timer (WDT).

### 15.1 Functional Overview

The WDT has two channels, ch. 0 and ch. 1, which are respectively for CA53 core 0 and core 1.

Of those, ch. 1 is for use with the ISP support package, so do not use registers related to this channel.

#### 15.1.1 Features

- Consists of a 32-bit counter driven by WDT\_CLK (48 MHz)
- The period counter can be set to values from 21.8453 msec to 89.4785 sec in 21.8453 msec units.
- Generates an interrupt request signal every cycle set in the WDT counter.
- If the software does not clear the interrupt factor by the time the next counter overflows after the interrupt request signal is generated, a reset request signal, WDTRSTB, is asserted.
- The settings of each register and WDT elapsed time (in cycles of WDT\_CLK) can be read.
- The counter operation and bus interface are asynchronous so operation does not depend on the lengths of the periods of the two clocks.
- Counting by the watchdog timer can be suspended by the CST and SYS (for debugging).

For details, see the section of SYS.

## 15.2 Pin Functions

### 15.2.1 List of Internal Pins

**Table 15.2-1** lists the internal pins.

Table 15.2-1 List of Internal Pins

| Classification    | Pin Name | I/O    | Function                                                                                                     |
|-------------------|----------|--------|--------------------------------------------------------------------------------------------------------------|
| WDT pin           | WDT_CLK  | Input  | WDT operating clock                                                                                          |
|                   | WDTRSTB  | Output | WDT reset output (level output)                                                                              |
|                   | WDTINT   | Output | WDT interrupt request output (level output)                                                                  |
| Count control pin | CNTSTOP  | Input  | When an ICE is in use in debugging the device, this terminal is used to stop the WDT in response to a break. |

## 15.2.2 Pin Reset Timing

### 15.2.2.1 Reset Control

PRESETn supports asynchronous inputs and internally uses a reset desynchronization circuit for each clock domain.

Do not access this circuit over the time  $2 \times \text{PCLK} + 2 \times \text{WDT\_CLK}$  after deassertion of PRESETn, as the reset desynchronization circuit will retain the reset for this time.

The PRDATA[31:0] pins are reset to the low level in synchronization with the PCLK clock. When a low level signal is input as the PRESETn signal as shown in **Figure 15.2-1**, low level signals (initial value) are output in synchronization with the rising edge of PCLK after the clock cycle in which the low-level PRESETn signal was input. PCLK is required to reset these pins.

The WDTINT pin is reset to the low level in synchronization with the WDT\_CLK clock. WDT\_CLK is required to reset this pin.

The WDTRSTB pin is asynchronously reset to the high level.

Figure 15.2-1 Reset Timing

### 15.2.3 Block Diagram

Figure 15.2-2 Block Diagram

15.2.4 Connection Configuration

Figure 15.2-3 Schematic of WDT Connection

## 15.3 Register Description

For the base addresses of the registers (<WDT0\_base> and <WDT1\_base>), see the section of Address Map.

### 15.3.1 List of Registers

The following is a list of the WDT registers. They can be read and written in 32-bit units.

Table 15.3-1 List of Registers

| Offset Address | Register Name                  | Abbreviation              | Initial Value | Access Unit (bits) |
|----------------|--------------------------------|---------------------------|---------------|--------------------|
| 000h           | WDT Control Register           | WDTm_WDTCNT* <sup>1</sup> | 0000_0000h    | 32                 |
| 004h           | WDT Period Setting Register    | WDTm_WDTSET* <sup>1</sup> | FFF0_0000h    | 32                 |
| 008h           | WDT Elapsed Time Register      | WDTm_WDTTIM* <sup>1</sup> | 0000_0000h    | 32                 |
| 00Ch           | WDT Interrupt Control Register | WDTm_WDTINT* <sup>1</sup> | 0000_0000h    | 32                 |

Note 1. m = 1, 0

### 15.3.2 Register Descriptions

The function description of each register is given below.

The prefix (WDTm\_) of the register names is omitted in the register descriptions and the field descriptions in this section.

#### 15.3.2.1 WDT Control Register (WDTm\_WDTCNT) (m = 0, 1)

This register is used to permit operation of the WDT function. Once software starts WDT, WDT does not stop\*<sup>1</sup> until it is reset by the PRESETn signal. Also, the WDT setting registers\*<sup>2</sup> cannot be changed. Setting the WDT setting register should be completed before permitting WDT operation\*<sup>3</sup>.

**Note 1.** The CNTSTOP signal may stop the internal counter temporarily.

**Note 2.** The WDT period setting register (WDTSET) and the WDT elapsed time register (WDTTIM).

**Note 3.** When the setting register is changed, wait until the setting register write data value is reflected before permitting WDT operation. The reflection time of the setting register is  $6 \times \text{PCLK} + 9 \times \text{WDT\_CLK}$  or more. If this reflection time is not kept, the value of the setting register is not reflected, and is ignored.

**Access Size:** 32 bits

**Address(es):** <WDT0\_S0\_base> + 0000h

<WDT1\_S0\_base> + 0000h

**Initial Value:** 0000\_0000h

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |       |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|
| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16    |
|               | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —     |
| Initial Value | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0     |
| R/W           | R  | R  | R  | R  | R  | R  | R  | R  | R  | R  | R  | R  | R  | R  | R  | R     |
| Bit           | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0     |
|               | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | WDTEN |
| Initial Value | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0     |

Table 15.3-2 WDTm\_WDTCNT Register Contents

| Bit Position | Bit Name | Description                                                                        |
|--------------|----------|------------------------------------------------------------------------------------|
| 31 to 1      | —        | Reserved. The write value should always be 0b.                                     |
| 0            | WDTEN    | WDT enable bit<br>0b: Invalid (nothing changes)<br>1b: WDT operation is permitted. |

15.3.2.2 WDT Period Setting Register (WDTm\_WDTSET) (m = 0, 1)

This register sets the period of a 32-bit counter that composes WDT. Writing is not possible during WDT operation. If written continuously, the data written later is valid. Use the following formula to calculate the WDT period.

WDT period = WDT\_CLK period × 1024 × 1024 × (the setting value of WDTTIME + 1)

Therefore,

the setting value of WDTTIME = WDT period / (WDT\_CLK period × 1024 × 1024) – 1

Access Size: 32 bits  
Address(es): <WDT0\_S0\_base> + 0004h  
<WDT1\_S0\_base> + 0004h  
Initial Value: FFF0\_0000h

|               |               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|---------------|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit           | 31            | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|               | WDTTIME[11:0] |    |    |    |    |    |    |    |    |    |    |    | —  | —  | —  | —  |
| Initial Value | 1             | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 0  | 0  | 0  | 0  |
| R/W           | RW            | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | R  | R  | R  | R  |
| Bit           | 15            | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|               | —             | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  |
| Initial Value | 0             | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| R/W           | R             | R  | R  | R  | R  | R  | R  | R  | R  | R  | R  | R  | R  | R  | R  | R  |

Table 15.3-3 WDTm\_WDTSET Register Contents

| Bit Position | Bit Name      | Description                                                               |
|--------------|---------------|---------------------------------------------------------------------------|
| 31 to 20     | WDTTIME[11:0] | WDT period setting value<br>Writing is not possible during WDT operation. |
| 19 to 0      | —             | Reserved. The write value should always be 0b.                            |

**Note:** When an interrupt occurs the value that WDT compares is WDTSET[31:0] + 000F\_FFFFh. Therefore, if the setting value of this register is 0010\_0000h, the interrupt occurrence count is 001F\_FFFFh (not 0010\_0000h).

15.3.2.3 WDT Elapsed Time Register (WDTm\_WDTTIM) (m = 0, 1)

This register indicates the 32-bit count value that composes WDT. If reading is performed during WDT operation, the elapsed time from clear to read may be read.

By writing to this register when the WDT is stopped, the value at the start of counting may be set to the 32-bit counter configuring the WDT. Writing is used for logic testing of the circuit. If WDT operation is started by writing a value greater than the counter period that is set in WDT period setting register (cleared value), after the 32-bit counter overflows and the value returns to 0b, WDT operates at the set correct period. Writing is not possible during WDT operation. If written continuously, the data written later is valid.

Table 15.3-4 WDTm\_WDTTIM Register Contents

| Bit Position | Bit Name      | Description                                                      |
|--------------|---------------|------------------------------------------------------------------|
| 31 to 0      | CRTTIME[31:0] | WDT count value<br>Writing is not possible during WDT operation. |

**Note:** When setting a value in the WDTTIM register, do not set a value that is WDTSET[31:0] register + F\_FFFFh.

### 15.3.2.4 WDT Interrupt Control Register (WDTm\_WDTINT) (m = 0, 1)

This register reads the WDT interrupt status, clears interrupt, and clears the counter that composes WDT. Set the INTDISP bit of this register to 1b within the time set by WDTSET. If not set, the WDTIT pin is asserted. After that, if the INTDISP bit is not further set to 1b within the time set by WDTSET, the WDTRSTB pin is asserted.

When the WDTINT register is accessed for consecutive writing, set a write interval of  $5 \times \text{PCLK} + 5 \times \text{WDT\_CLK}$  or more. If the write interval is not kept, the register is not written.

**Access Size:** 32 bits

**Address(es):** <WDT0\_S0\_base> + 000Ch

<WDT1\_S0\_base> + 000Ch

**Initial Value:** 0000\_0000h

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|               | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  |
| Initial Value | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

| 0            | INTDISP  | Read and clear interrupt status<br>[Read] Interrupt status<br>0b: No interrupt<br>1b: With interrupt<br>[Write] Interrupt clear<br>0b: Invalid (nothing changes)<br>1b: Interrupt clear |

## 15.4 Operations

The first time the counter overflows, the WDT outputs an interrupt signal, and when the counter overflows for a second time without having been cleared, the WDT outputs a reset request signal.

The prefix (WDTm\_) of the register names is omitted in this and subsequent sections.

### 15.4.1 Operation Timing

Figure 15.4-1 WDT Output Signal Operation Timing

### 15.4.2 Provisions for the Write Access Interval of a WDT Interrupt Control Register (WDTINT)

On completion of write access to a WDT interrupt control register, a synchronization period is required for synchronization of the written data with WDT\_CLK. Consecutive writing to a WDTINT register requires a write interval\*<sup>1</sup> of at least  $5 \times \text{PCLK} + 5 \times \text{WDT\_CLK}$  before a next write access.

**Note 1.** If condition for the write interval is not satisfied, the interrupt request may not be cleared. In this case, make sure that the interrupt factor has been cleared after write access before proceeding with a next write access.

Figure 15.4-2 Provisions for the Write Access Interval of WDTINT

### 15.4.3 Timing of Reflection of Register Settings in WDT Operation

The registers other than the WDT interrupt control register (WDTINT) are always synchronized with WDT\_CLK running at a fixed period.

Depending on the specifications of the synchronization circuit, the time taken until written data are reflected in the WDT operation is in the range from  $2 \times \text{PCLK} + 4 \times \text{WDT\_CLK}$  (minimum) to  $6 \times \text{PCLK} + 9 \times \text{WDT\_CLK}$  (maximum). **Figure 15.4-3** shows the minimum synchronization interval for written data. **Figure 15.4-4** shows the maximum synchronization interval for written data.

Figure 15.4-3 Timing 1 of Reflection of Register Settings in WDT Operation

Figure 15.4-4 Timing 2 of Reflection of Register Settings in WDT Operation

#### 15.4.4 Timing of Reflection of the WDT Counter Value in the WDTTIM Register

The storage of values in the WDTTIM register is of counter values in synchronization with PCLK. Therefore, the interval after which a value is updated in the WDTTIM register is up to  $5 \times \text{WDT\_CLK} + 5 \times \text{PCLK}$ , which means that the value prior to the actual counter value may be read during this interval.

Figure 15.4-5 Timing of Reflection of the Counter Value in the WDTTIM Register

## 15.5 Usage Notes

- When setting values in the WDTTIM register, do not set the value of the WDTSET[31:0] register + F\_FFFFh.
- The reset request signal, WDTRSTB, and the WDT interrupt signal, WDTINT, cannot be masked.

## Section 16 Compare-Match Timer (TIM)

This section describes the functions of the compare match timer (TIM).

### 16.1 Functional Overview

The TIM has an internal 32-bit counter that can be used as an interval timer.

This LSI has a total of 32 channels of TIM from ch. 0 to ch. 31.

Among these channels, ch. 0 to ch. 7 and ch. 24 to ch. 31 are used by the ISP support package. Therefore, do not use the registers related to the target channels.

#### 16.1.1 Features

- Configured with a 32-bit counter operating at INCLOCK (2 MHz)
- The clock input from the count clock input pin can be divided by 2, 4, 8, 16, 32, 64, 128, or 256, and one of these divided clocks can be used as the count clock.
- The counter period can be set in the range of 1 to 4294967296 (32-bit timer) using the selected divider clock as the count clock.
- Generates an interrupt request signal every cycle set in the TIM counter.
- The counter operation and the bus interface are asynchronous and can operate independently regardless of the size of the respective clock cycles.

#### CAUTION

---

The interrupt request signal should be used in level output mode (the INTMODE field in the TIMm\_TMCD register should be set to 1b).

---

### 16.1.2 Block Diagram

Figure 16.1-1 Block Diagram

## 16.2 Pin Functions

### 16.2.1 List of Internal Pins

**Table 16.2-1** lists the internal pins of the TIM.

Table 16.2-1 List of Internal Pins

| Classification | Pin Name | I/O    | Function                       |
|----------------|----------|--------|--------------------------------|
| Count Clock    | INCLOCK  | Input  | Counting clock                 |
| Interrupt      | INTCMD   | Output | Match interrupt request signal |

## 16.3 Register Description

For the base addresses of the registers (<TIM0\_S0\_base> to <TIM31\_S0\_base>), see the section of Address Map.

### 16.3.1 List of Registers

The following is a list of the timer registers.

Table 16.3-1 List of Registers

| Offset Address | Register Name                  | Abbreviation | Initial Value | Access Unit (bits) |
|----------------|--------------------------------|--------------|---------------|--------------------|
| 000h           | Timer Counter Register         | TIMm_TMD     | 0000_0000h    | 32                 |

### 16.3.2 Register Descriptions

The function description of each register is described below.

#### 16.3.2.1 Timer Counter Register (TIMm\_TMD) (m = 0 to 31)

This register is a 32-bit up counter, and starting and stopping are controlled by the CE bit of the control register (TIMm\_TMCD).

For the count clock, the INCLOCK input is divided by the built-in frequency divider. INCLOCK /2, INCLOCK /4, INCLOCK /8, INCLOCK /16, INCLOCK /32, INCLOCK /64, INCLOCK /128, INCLOCK /256 can be selected from CS0-CS2 of TIMm\_TMCD. This register can only be read.

*Note:* The TMD value is read out synchronized with PCLK. Therefore, a value before the actual count value may be read.

**Access Size:** 32 bits

**Address(es):**

|                         |                         |

| Bit Position | Bit Name  | Description                                                                                                                                                                                                                                                                                   |
|--------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | TMD[31:0] | Count value<br>TMD = 0000_0000h under any of the following conditions. <ul style="list-style-type: none"> <li>– Timing when a low is input to the PRESETn pin</li> <li>– Timing when the CE bit of TIMm_TMCD register is set to 0b</li> <li>– Timing when TMD and CMD values match</li> </ul> |

**CAUTIONS**

---

1. Do not change the divided clock setting while the timer is operating.
  2. When changing the divided clock setting, set CE = 0b before executing.
  3. The CE bit is synchronized with INCLOCK after being written from the APB bus, there is a time lag between the time CE = 1b is written and TMD is activated.
  4. This is a read-only register, writing is prohibited.
-

### 16.3.2.2 Timer Compare Register (TIMm\_CMD) (m = 0 to 31)

This register compares the count value of the TIMm\_TMD register and generates an interrupt request signal (INTCMD) if they match. TIMm\_TMD is cleared in synchronization with this match. The set value of this register is used as the counter comparison value after synchronizing with INCLOCK.

The INTCMD occurrence cycle can be calculated using the following formula.

$$\text{INTCMD generation cycle (sec)} = \frac{1}{\text{INCLOCK frequency (Hz)}} \times 2^{(N+1)} \times (\text{CMD} + 1)$$

N: CS[2:0] set value for TIMm\_TMCD register

CMD: Set the value for TIMm\_CMD register\*1

**Note 1.** (CMD + 1) when CMD is set to 0b is as follows and 4294967296 + 1 for the 32-bit timer.

**Access Size:** 32 bits

**Address(es):**

Table 16.3-3 TIMm\_CMD Register Contents

| Bit Position | Bit Name  | Description            |
|--------------|-----------|------------------------|
| 31 to 0      | CMD[31:0] | Count comparison value |

**Note:**

- The written value will be reflected after INCLOCK synchronization. There will be a time lag (refer to **Table 16.3 3a** below) for the maximum (latest) timing from when the write to the register is completed until the write value is reflected in the timer operation.

Table 16.3-3a Operation Reflection Timing of Register Setting Value

| Register Name | Software Operation         | Timer Stopped                                    | Timer Running                                                                                     |
|---------------|----------------------------|--------------------------------------------------|---------------------------------------------------------------------------------------------------|
| TIMm_CMD      | Compare value setting      | $1 \times \text{PCLK} + 3 \times \text{INCLOCK}$ | Counter clear timing after compare matches after $1 \times \text{PCLK} + 3 \times \text{INCLOCK}$ |
| TIMm_TMCD     | Count start                | Same as above                                    | Same as above                                                                                     |
|               | Count pause                | Same as above                                    | Same as above                                                                                     |
|               | Resume from counting pause | Same as above                                    | Same as above                                                                                     |
|               | Count stop                 | Same as above                                    | Same as above                                                                                     |
| TIMm_INTCLR   | Clear interrupt            | Same as above                                    | Same as above                                                                                     |

- The read value will be the value after INCLOCK synchronization. Since synchronization takes time, there will be a time lag before the set value can be read. Refer to **Table 16.3 3b** below for the maximum (latest) timing from when the write to the register is complete until the written value can be read.

Table 16.3-3b Register Read Enable Timing

| Register Name | Software Operation         | Timer Stopped                                    | Timer Running                                    |
|---------------|----------------------------|--------------------------------------------------|--------------------------------------------------|
| TIM_CMD       | Compare value setting      | $5 \times \text{PCLK} + 5 \times \text{INCLOCK}$ | $5 \times \text{PCLK} + 5 \times \text{INCLOCK}$ |
| TIM_TMCD      | Count start                | Same as above                                    | Same as above                                    |
|               | Count pause                | Same as above                                    | Same as above                                    |
|               | Resume from counting pause | Same as above                                    | Same as above                                    |
|               | Count stop                 | Same as above                                    | Same as above                                    |

- If the CMD value is rewritten during the timer operation, the new CMD value is reflected when the counter (TMD) matches the previous CMD setting value.
- When writing to CMD, follow the rules for the writing interval. Write will be ignored if not followed.
- The relationship between the CMD setting value and the count number is shown in **Table 16.3 3c** below (as the 32-bit configuration).

Table 16.3-3c Relationship between CMD Setting Value and Count Number (32-bit Configuration)

| CMD Setting Value (32-bit Timer) | Count Value        | Description                                                 |
|----------------------------------|--------------------|-------------------------------------------------------------|
| 0h                               | 1_0000_0000h times | Maximum setting 0->1->2...FFFF_FFFFh->1_0000_0000h->0->1... |

| 1            | CE       | The counter enable (CE) bit controls the operation of the divider and timer counter. When CE = 0b is set, the divider and timer counters are initialized.<br>0b: The frequency divider and counter are initialized to 0b and stopped.<br>1b: The divider and counter operate. |

Table 16.3-4 TIMm\_TMCD Register Contents (2/2)

| Bit Position | Bit Name | Description                                                                                                                                                                                                                                                                                                                     |
|--------------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | CAE      | <p>The clock action enable (CAE) bit controls the operation of the count clock (INCLOCK) divider. The purpose of this function is to pause the counter during a break when debugging with ICE. Set to 1b for normal use.</p> <p>0b: Pauses the count clock (INCLOCK) divider.<br/>1b: Return from the pause of the divider.</p> |

Note 1. Do not change CS[2:0] while the timer is operating. To change it, set CE to 0b before executing. If CS[2:0] is rewritten during operation, the operation cannot be guaranteed.

Note 2. The timer/counter count cycle selection is shown below.

Table 16.3-5 Selection of Timer/Counter Count Cycle

| CS2 | CS1 | CS0 | Count Enable Select                                |
|-----|-----|-----|----------------------------------------------------|
| 0b  | 0b  | 0b  | Select INCLOCK divide-by-2 signal as count clock   |
| 0b  | 0b  | 1b  | Select INCLOCK divide-by-4 signal as count clock   |
| 0b  | 1b  | 0b  | Select INCLOCK divide-by-8 signal as count clock   |
| 0b  | 1b  | 1b  | Select INCLOCK divide-by-16 signal as count clock  |
| 1b  | 0b  | 0b  | Select INCLOCK divide-by-32 signal as count clock  |
| 1b  | 0b  | 1b  | Select INCLOCK divide-by-64 signal as count clock  |
| 1b  | 1b  | 0b  | Select INCLOCK divide-by-128 signal as count clock |
| 1b  | 1b  | 1b  | Select INCLOCK divide-by-256 signal as count clock |

### 16.3.2.4 Timer Interrupt Clear Register (TIMm\_INTCLR) (m = 0 to 31)

This register clears the interrupt request signal (INTCMD). When reading for writing only, 0b can be read.

*Note:* When writing to the TIMm\_INTCLR register, be sure to observe the write interval rules. Write will be ignored if not followed. Clear is prioritized if write to the TIMm\_INTCLR register and timer interrupt occurs simultaneously.

**Access Size:** 32 bits

**Address(es):**

|                         |                         |

| Bit Position | Bit Name | Description                                                                   |
|--------------|----------|-------------------------------------------------------------------------------|
| 31 to 1      | —        | Reserved. These bits are read as 0b. The write value should be always 0b.     |
| 0            | INTCLR   | Clears the interrupt.<br>0b: No action<br>1b: Clears interrupt request signal |

## 16.4 Operation

The prefix (TIMm\_) of the register names is omitted in this and subsequent sections.

### 16.4.1 Notes on Write Interval

When the software writes to the same register of the timer, some precautions should be taken regarding the write interval. Follow the precautions when using this product. If the precautions are not followed, writing to the registers will be ignored.

<Write interval>

Clock notation:  $5 \times \text{PCLK} + 5 \times \text{INCLOCK}$

Time notation:  $5 \times (1/\text{PCLK frequency (Hz)}) + 5 \times (1/\text{INCLOCK frequency (Hz)})$

Allow an interval of at least the number described above for writing.

Figure 16.4-1 Notes on Write Interval

16.4.2 Clock and Reset Supply Procedure

As the reset is released synchronously with PCLK, supply it according to the following procedure.

Figure 16.4-2 Clock Supply Procedure

16.4.3 Timer Startup Procedure

This section describes the procedure for starting the timer. Make sure to use the product according to this procedure.

Figure 16.4-3 Timer Startup Procedure (for Writing One Time to TMCD)

Figure 16.4-4 Timer Startup Procedure (When Writing to TMCD in Multiple Times)

### 16.4.4 Procedure for Stopping the Timer

This section describes the procedure for stopping the timer.

Figure 16.4-5 Procedure for Stopping the Timer

### 16.4.5 Procedure for Changing the Operation Clock of the Timer

The following is the procedure for changing the operation clock of the timer.

Figure 16.4-6 Procedure for Changing the Timer Operation Clock (Counter Operation and Clock Supply Stop)

### 16.4.6 Procedure for Changing the Compare Value of a Timer

This section describes the procedure for changing the compare value of a timer. If the value is changed while the timer is running, the change will be reflected when the timer interrupt is issued.

Figure 16.4-7 Procedure for Changing the Compare Value of a Timer (Changing While the Timer is Running)

Figure 16.4-8 Procedure for Changing the Compare Value of a Timer (After the Timer is Stopped)

### 16.4.7 Timer Operation

A time lag occurs when writing registers and capturing timer count values, due to the passing of signals between asynchronous clocks.

#### 16.4.7.1 Operation Reflection Timing of Register Setting Values

The following indicates the maximum (slowest) timing between the completion of a write to the register and the time when the write value is reflected in the timer operation.

Table 16.4-1 Operation Reflection Timing of Register Setting Values

| Register Name | Software Operation      | Timer is Stopped                                 | Timer is Running                                                                                      |
|---------------|-------------------------|--------------------------------------------------|-------------------------------------------------------------------------------------------------------|
| CMD           | Compare value setting   | $1 \times \text{PCLK} + 3 \times \text{INCLOCK}$ | Counter clear timing after a compare match following $1 \times \text{PCLK} + 3 \times \text{INCLOCK}$ |
| TCMD          | Count start             | Same as above                                    | Same as above                                                                                         |
|               | Count pause             | Same as above                                    | Same as above                                                                                         |
|               | Resume from count pause | Same as above                                    | Same as above                                                                                         |
|               | Count stop              | Same as above                                    | Same as above                                                                                         |
| INTCLR        | Interrupt clear         | Same as above                                    | Same as above                                                                                         |

#### 16.4.7.2 Readable Timing of Register Set Value

The following indicates the maximum (slowest) timing between the completion of a write to the register and the time when the written value can be read.

Table 16.4-2 Readable Timing of Register

| Register Name | Software Operation      | Timer is Stopped                                 | Timer is Running                                 |
|---------------|-------------------------|--------------------------------------------------|--------------------------------------------------|
| CMD           | Compare value setting   | $5 \times \text{PCLK} + 5 \times \text{INCLOCK}$ | $5 \times \text{PCLK} + 5 \times \text{INCLOCK}$ |
| TCMD          | Count start             | Same as above                                    | Same as above                                    |
|               | Count pause             | Same as above                                    | Same as above                                    |
|               | Resume from count pause | Same as above                                    | Same as above                                    |
|               | Count stop              | Same as above                                    | Same as above                                    |

16.4.7.3 Count Start Timing

Figure 16.4-9 Count Start Timing

16.4.7.4 Count Stop Timing

Figure 16.4-10 Count Stop Timing

### 16.4.7.5 Clear signal (INTCLR) Synchronization Reflection Timing

The clear signal is a 1-bit pulse signal.

Figure 16.4-11 Reflection Timing of Clear Signal (INTCLR) to INCLOCK Synchronization Register

### 16.4.7.6 Reflection Timing of Count Value (TMD) to PCLK Synchronization Register

This register has a copy of the count value (TMD) of a timer running with the synchronization of INCLOCK, synchronizes the value of the copy with PCLK, and holds it in a register for reading. When a read is received from the APB bus, the register value for the read is returned. During the period when the count value operating with the synchronization of INCLOCK is synchronized with PCLK, the count value is held. Therefore, the value differs from the actual count value (TMD).

Figure 16.4-12 Reflection Timing of TMD Value to PCLK Synchronization Register

### 16.4.7.7 Operation Start Condition

The operation is started by writing  $\text{TMCD:CE} = 1\text{b}$  and  $\text{CAE} = 1\text{b}$ . The set values of CE and CAE and the operation of the counter are as follows.

Table 16.4-3 CE, CAE Setting Values and Internal Counter Operation

| CE | CAE | Operation                                             |
|----|-----|-------------------------------------------------------|
| 1b | 1b  | Executes counting operation at rising edge of INCLOCK |
| 1b | 0b  | Counter pauses (for debugging with ICE)               |
| 0b | 1b  | Counting operation stopped (the counter value is 0)   |
| 0b | 0b  | Counting operation stopped (the counter value is 0)   |

- INTCMD output timing

INTCMD can be set pulse mode and level mode by the register. In pulse mode, it is active for one INCLOCK period starting from the rising edge of the next INCLOCK after the TMD and CMD slaves are matched. In level mode, it will remain active until it is cleared.

Figure 16.4-13 INTCMD Operation Timing (Pulse Mode)

Figure 16.4-14 INTCMD Operation Timing (Level Mode)

## Section 17 Pulse-Width Modulation Timer (PWM)

This section describes the functions of the pulse-width modulation timer (PWM).

### 17.1 Functional Overview

The PWM has a total of 16 channels from ch. 0 to ch. 15. Of those, ch. 0 to ch. 7 and ch. 15 are for use with the ISP support package, so do not use registers related to those channels.

#### 17.1.1 Features

- The PWM has 24-bit counters which operate at PWM\_CLK (48 MHz).
- The frequency division ratio for internal counter operation is selectable as PWM\_CLK divided by 1, 16, 256, or 2048.
- The period as well as the duty cycle is adjustable.
- The low-level and high-level order of the PWM signals can be inverted.
- The duty cycle of the PWM signal is selectable in the range from 0 to 100%.
- The period of the PWM signal is selectable in the range from 2.4 Hz to 480 kHz.
- The minimum resolution is 20.83 ns.
- Three interrupt sources: Rising and falling edges of the PWM signal and clearing of the counter
- Counter operation and the bus interface are asynchronous and both can operate independently of the magnitude relationship of the respective clock periods.

17.1.2 Block Diagram

Figure 17.1-1 Block Diagram

17.1.3 Connection Configuration

Figure 17.1-2 shows the connection diagram of the PWM.

Figure 17.1-2 Schematic of the PWM Connection

## 17.2 Pin Functions

### 17.2.1 List of Internal Pins

**Table 17.2-1** lists the internal pins of the PWM.

Table 17.2-1 List of Internal Pins

| Classification   | Pin Name | I/O    | Function                                                                                                                 |
|------------------|----------|--------|--------------------------------------------------------------------------------------------------------------------------|
| PWM Related Pins | PWM_CLK  | Input  | PWM Counter Operating Clock                                                                                              |

### 17.2.1.1 How to Control Resetting

PRESETn is an asynchronous input and internally works with the synchronous reset release circuits per clock domain. After the de-assertion of PRESETn, do not attempt access during the period  $2 \times \text{PCLK} + 2 \times \text{PWM\_CLK}$  as the synchronous reset release circuit leaves the reset retained over this period.

The PRDATA[31:0] pins are reset to the low level in synchronization with the PCLK clock. As shown in **Figure 17.2-1**, when the low level is input to the PRESETn signal, the low level (the initial value) is output after one clock cycle in synchronization with the rising edge of PCLK. Resetting these pins requires PCLK.

The PWMINT pin is reset to the low level in synchronization the WM\_CLK clock. Resetting this pin requires PWM\_CLK.

The PWM pin is reset to the low level asynchronously with the clock.

Figure 17.2-1 Reset Timing

### 17.2.1.2 Interrupt Timing

The figure below shows the timings of output of the three types of interrupt, rising and falling edges of the PWM signal and clearing of the counter.

Figure 17.2-2 Interrupt Output Timing

## 17.3 Register Descriptions

For the register base addresses (<PWM0\_S0\_base> to <PWM15\_S0\_base>), see the section of Address Map.

### 17.3.1 List of Registers

**Table 17.3-1** lists the registers.

Table 17.3-1 List of Registers

| Offset Address | Register Name                        | Abbreviation*1 | Initial Value | Access Unit (bits) |
|----------------|--------------------------------------|----------------|---------------|--------------------|
| 000h           | PWM control register                 | PWMm_PWMCTR    | 0000_0000h    | 32                 |
| 004h           | PWM cycle setting register           | PWMm_PWMCYC    | 0000_0000h    | 32                 |
| 008h           | PWM low-level width setting register | PWMm_PWMLOW    | 0000_0000h    | 32                 |
| 00Ch           | PWM counter register                 | PWMm_PWMCNT    | 0000_0000h    | 32                 |
| 010h           | PWM interrupt enable register        | PWMm_PWMIEN    | 0000_0000h    | 32                 |
| 014h           | PWM interrupt register               | PWMm_PWMINT    | 0000_0000h    | 32                 |
| 018h to 01Ch   | Reserved area                        | Reserved       | Undefined     | 32                 |

Note 1. m = 0 to 15

### 17.3.2 Register Descriptions

The function of each register is given below.

#### 17.3.2.1 PWM Control Register (PWMm\_PWMCTR) (m = 0 to 15)

This register controls the PWM operation.

**Access Size:** 32 bits

**Address(es):** <PWM0\_S0\_base> + 0000h <PWM8\_S0\_base> + 0000h  
 <PWM1\_S0\_base> + 0000h <PWM9\_S0\_base> + 0000h  
 <PWM2\_S0\_base> + 0000h <PWM10\_S0\_base> + 0000h  
 <PWM3\_S0\_base> + 0000h <PWM11\_S0\_base> + 0000h  
 <PWM4\_S0\_base> + 0000h <PWM12\_S0\_base> + 0000h  
 <PWM5\_S0\_base> + 0000h <PWM13\_S0\_base> + 0000h  
 <PWM6\_S0\_base> + 0000h <PWM14\_S0\_base> + 0000h  
 <PWM7\_S0\_base> + 0000h <PWM15\_S0\_base> + 0000h

**Initial Value:** 0000\_0000h

|               |    |    |    |    |    |    |    |    |    |    |    |    |       |       |           |      |

| 0            | PWMS      | The PWM output value can be read.                                                                                                                                                                                                          |

**Note:** The relationship between PWMTM bit and PWME bit is shown in **Table 17.3-2a**.

Table 17.3-2a

| PWMTM | PWME | Description                                                                     |
|-------|------|---------------------------------------------------------------------------------|
| 1     | X    | Any count value can be set in the PWMm_PWMCNT register, which is a PWM counter. |
| 0     | 0    | Counter is stopped and cleared.                                                 |
| 0     | 1    | Counter is counting up.                                                         |

**Note:** x = Don't care

### 17.3.2.2 PWM Cycle Setting Register (PWMm\_PWMCYC) (m = 0 to 15)

This register is a 24-bit register that sets the cycle of the counter that generates PWM output. The setting value to the PWMm\_PWMCYC register is obtained by the following formula.

$$\text{PWMm\_PWMCYC register setting value} = (\text{PWM period (ns)} / (\text{PWM\_CLK period (ns)} \times \text{Division ratio})) - 1$$

(Ex) When the period of the counter that generates PWM is 100,000,000 ns (10 Hz), the period of PWM\_CLK is 20.8333 ns (48 MHz), and the PWM\_CLK division setting is 1, the setting value of the PWMm\_PWMCYC register is as follows.

$$\begin{aligned} \text{PWMm\_PWMCYC register} &= (100,000,000\text{ns} / (20.8333\text{ ns} \times 1)) - 1 \\ \text{setting value} &= 4,800,000 \\ &= 493\text{E}00\text{h} \end{aligned}$$

**Note:** To change the setting value of the PWM cycle setting register (PWMm\_PWMCYC), set the PWME bit of the PWM control register (PWMm\_PWMCTR) to 0b and stop the counter operation. If it is changed during counter operation, PWM output may not be performed correctly.

**Access Size:** 32 bits

**Address(es):** <PWM0\_S0\_base> + 0004h <PWM8\_S0\_base> + 0004h

|--------------|--------------|---------------------------------------------------------------------------|
| 31 to 24     | —            | Reserved. These bits are read as 0b. The write value should always be 0b. |
| 23 to 0      | PWMCYC[23:0] | Counter cycle value                                                       |

### 17.3.2.3 PWM Low Width Setting Register (PWMm\_PWMLOW) (m = 0 to 15)

This is a 24-bit register that sets the low pulse width of the PWM signal.

When the count clock source PWM\_CLK = 100 [MHz], the low pulse width with a resolution of 10 [ns] can be registered. When the counter value matches the value set in the PWMLOW register, the PWM output goes high at the next clock rise. If the counter value is less than or equal to the value set in the PWMLOW register, the PWM output goes low at the next clock rise. If the PWMLOW register is changed during counter operation, the set value becomes valid after the current PWM cycle ends.

The setting value of the PWMm\_PWMLOW register is obtained by the following formula.

Setting value of PWMm\_PWMLOW register = PWMm\_PWMCYC register setting value (decimal) × Low pulse width ratio (%)

(Ex) When the setting value of the PWMm\_PWMCYC register 9,999,999 (counter frequency to generate PWM 10 [Hz]) and the low pulse width ratio is 90%, the setting value of the PWMm\_PWMLOW register is as follows.

$$\begin{aligned}\text{PWMm\_PWMLOW register} &= 9,999,999 \times 0.90 \\ \text{setting value} &= 8,999,999.1 \\ &= 89543\text{Fh}\end{aligned}$$

The same calculation is performed as follows.

When PWMm\_PWMLOW register = 000000h, low : high = 0 : 100 (low width 0%)

When PWMm\_PWMLOW register = 4C4B3Fh, low : high = 50 : 50 (low width 50%)

When PWMm\_PWMLOW register = 89543Fh, low : high = 90 : 10 (low width 90%)

When PWMm\_PWMLOW register > 98967Fh, low : high = 100 : 0 (low width 100%)

**Access Size:** 32 bits

**Address(es):** <PWM0\_S0\_base> + 0008h <PWM8\_S0\_base> + 0008h  
<PWM1\_S0\_base> + 0008h <PWM9\_S0\_base> + 0008h  
<PWM2\_S0\_base> + 0008h <PWM10\_S0\_base> + 0008h  
<PWM3\_S0\_base> + 0008h <PWM11\_S0\_base> + 0008h  
<PWM4\_S0\_base> + 0008h <PWM12\_S0\_base> + 0008h  
<PWM5\_S0\_base> + 0008h <PWM13\_S0\_base> + 0008h  
<PWM6\_S0\_base> + 0008h <PWM14\_S0\_base> + 0008h  
<PWM7\_S0\_base> + 0008h <PWM15\_S0\_base> + 0008h

**Initial Value:** 0000\_0000h

Table 17.3-4 PWMm\_PWMLOW Register Contents

| Bit Position | Bit Name     | Description                                                               |
|--------------|--------------|---------------------------------------------------------------------------|
| 31 to 24     | —            | Reserved. These bits are read as 0b. The write value should always be 0b. |
| 23 to 0      | PWMLOW[23:0] | Sets the low level pulse width of the PWM signal.                         |

### 17.3.2.4 PWM Counter Register (PWMm\_PWMCNT) (m = 0 to 15)

When the PWMm\_PWMCNT register is read, the PWM counter value can be read.

The counter counts up when the PWMTM bit in the PWMCTR register = 0 and the PWME bit in the PWMm\_PWMCTR register = 1, and continues to count up within the range set by the PWMm\_PWMCYC register.

When the PWMTM bit in the PWMm\_PWMCTR register is 0b and the PWME bit in the PWMm\_PWMCTR register is 0b, the count is stopped and the count value is 0b.

Since the PWMm\_PWMCNT register stores the count value synchronized with PCLK, the value before the actual count value is read.

This register can be written only when PWMTM bit = 1 (PWM counter setting) in the PWMm\_PWMCTR register is set. Note that when the PWMCNT bit is set to 0b with the PWMTM bit = 1 (PWM counter setting) or the count value is set to 0b and the counter is stopped (PWME bit = 0 in the PWMm\_PWMCTR register), the counter clear interrupt is not generated.

**Access Size:** 32 bits

**Address(es):** <PWM0\_S0\_base> + 000Ch <PWM8\_S0\_base> + 000Ch  
 <PWM1\_S0\_base> + 000Ch <PWM9\_S0\_base> + 000Ch  
 <PWM2\_S0\_base> + 000Ch <PWM10\_S0\_base> + 000Ch  
 <PWM3\_S0\_base> + 000Ch <PWM11\_S0\_base> + 000Ch  
 <PWM4\_S0\_base> + 000Ch <PWM12\_S0\_base> + 000Ch  
 <PWM5\_S0\_base> + 000Ch <PWM13\_S0\_base> + 000Ch

| Bit Position | Bit Name     | Description                                                               |
|--------------|--------------|---------------------------------------------------------------------------|
| 31 to 24     | —            | Reserved. These bits are read as 0b. The write value should always be 0b. |
| 23 to 0      | PWMCNT[23:0] | The counter value of PWM can be read. It counts up with PWM_CLK.          |

### 17.3.2.5 PWM Interrupt Enable Register (PWMm\_PWMIEN) (m = 0 to 15)

This register enables or disables output to the interrupt request output signal (PWMINT) for three interrupt factors. Multiple bits can be set at the same time.

**Access Size:** 32 bits

**Address(es):** <PWM0\_S0\_base> + 0010h <PWM8\_S0\_base> + 0010h  
 <PWM1\_S0\_base> + 0010h <PWM9\_S0\_base> + 0010h  
 <PWM2\_S0\_base> + 0010h <PWM10\_S0\_base> + 0010h

### 17.3.2.6 PWM Interrupt Register (PWMm\_PWMINT) (m = 0 to 15)

This register monitors and clears the interrupt status.

When reading, the interrupt status can be monitored. When writing, the interrupt is cleared by writing 1b. When 0b is written, the interrupt will not be cleared.

**Access Size:** 32 bits

## 17.4 Function Details

The prefix (PWMm\_) of the register names is omitted in this and subsequent sections.

### 17.4.1 PWM Signal Output

Figure 17.4-1 PWM Pin Operation Timing

The counter counts up from `00_0000h` on the rising edge of `PWM_CLK`. It is cleared when its value matches the value of the `PWMCYC` register and counts up again from `00_0000h` until its value matches that of the `PWMCYC` register. After that, the counter repeats this operation.

Figure 17.4-2 PWM Output Timing Details

The counter starts counting up on the rising edge of PWM\_CLK when the PWME bit of the PWM control register (PWMCTR) is set to 1. The PWM signal remains at the low level until counting starts. When the counter value matches the value of the PWMLOW register, the PWM output is driven to high on the next rising edge of the clock.

The output level (low or high) setting of the PWM signal can be set by using the PWMHL bit of the PWM control register (PWMCTR) and the PWM signal is inverted and output if the output level setting of the PWM signal is 1 (i.e., the PWMHL bit = 1).

**Figure 17.4-2** shows the respective timings of the PWM signal when the output level setting of the PWM signal is 0 (PWMHL = 0b), the PWMLOW register values are 3 and 0 (the duty cycle is 100%), when the PWMLOW register value is equal to that of the PWMCYC register, and when the PWMLOW register value is greater than the PWMCYC register value (the duty cycle is 0%).

### 17.4.2 Changing the Duty Cycle

Changing the duty cycle is possible by modifying the PWMLOW register value and changing the pulse width at low level. The duty cycle becomes 0% for the low width when the value of the PWMLOW register is 0000\_0000h and 100% for the low width when the value of the PWMLOW register value is greater than that of the PWM cycle setting register (PWMCYC).

The PWMLOW register value can be changed even while the PWM is operating. The changed PWMLOW register value is reflected in the pulse width at low level of the next PWM cycle as shown in **Figure 17.4-1**. If the PWMLOW register is read immediately after it has been set, the new value may be read even before the PWM is operating in the way which reflects the changed value.

### 17.4.3 Stipulation on the Interval of Writing to the PWM Interrupt Register (PWMINT)

Following the completion of write access to the PWM interrupt register (PWMINT), a period for synchronization is required to synchronize the written data with PWM\_CLK. In write access to the PWMINT register, an interval\*<sup>1</sup> of at least  $5 \times \text{PCLK} + 5 \times \text{PWM\_CLK}$  is required between writing once access and writing the next time.

**Note 1.** If the interval of writing is not secured, the interrupt request signal may not be de-asserted.  
In such cases, confirm that the interrupt source has been de-asserted after writing before proceeding with the next writing.

Figure 17.4-3 Stipulation on the Interval of Writing to the PWMINT Register

### 17.4.4 Timing at which Register Values are Reflected in PWM Operation

The registers other than the PWM interrupt register (PWMINT) are always synchronized with PWM\_CLK at regular intervals.

It takes some time (Min:  $2 \times \text{PCLK} + 4 \times \text{PWM\_CLK}$  to Max:  $6 \times \text{PCLK} + 9 \times \text{PWM\_CLK}$ ) for the value set in the register to be reflected in the PWM circuit because there is a synchronizer between the register and the PWM circuit.

**Figure 17.4-4** shows how the written data are synchronized at the minimum period. **Figure 17.4-5** shows how the written data are synchronized at the maximum period.

Figure 17.4-4 Timing 1 at which Register Values are Reflected in PWM Operation

Figure 17.4-5 Timing 2 at which Register Values are Reflected in PWM Operation

#### 17.4.5 Timing at which the PWM Operating Status Value is Reflected in a Register

The values to be stored in the PWMS bit of the PWMCTR register, in the PWMCNT register, and in the PWMINT register are stored in synchronization with PCLK. Accordingly, the interval at which the value is updated in each register is up to  $5 \times \text{PWM\_CLK} + 5 \times \text{PCLK}$ , and until this has elapsed the previous value may be read as the actual PWM operating status value.

## 17.5 Points for Caution

- (1) When the setting of the PWM cycle setting register (PWMCYC) is to be changed, do so after setting the PWME bit of the PWM control register (PWMCTR) to 0 to stop counter operation. If the setting is changed during counter operation, PWM output may not proceed correctly.
- (2) In the case of write access to the output level setting register for the PWM signal (the PWMHL bit of the PWMCTR register) to change its setting, the changed setting is reflected in the output level of the PWM signal at the time when the written data are synchronized with PWM\_CLK, which is derived from PCLK.

## Section 18 Real-Time Clock (RTC)

This section describes the functions of the real-time clock (RTC).

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 18.1 Functional Overview

The RTC unit is a real-time clock module which runs with the backup power supply.

This LSI chip includes an oscillation circuit for a real-time clock (use of the RTC requires the external connection of a 32.768-kHz crystal resonator).

- The RTC has a 32-bit seconds counter and a 23-bit startup timer (seconds counter).
- The RTC has an interface with the external power supply sequence controller (PWC) so that it can be used as the startup timer.\*<sup>1</sup>
- The clock function is available.

**Note 1.** If the external power supply sequence is controlled by the PWC, the system can be restarted after the specified time by operating the startup timer of the RTC before turning the system power supply off.

## Section 19 DMA Controller (DMAC)

This section describes the functions of the DMA controller (DMAC).

### 19.1 Functional Overview

The DMAC controller (DMAC) is made up of DMAC0 and DMAC1 (each having eight channels).

It supports hardware activation, software activation, and link transfer with the use of descriptors. Of the two units, eight channels of DMAC1 are for use with the ISP support package, so do not use registers related to those channels.

#### 19.1.1 Features

- The bank switching setting in SYS allows access to the address space over 4 Gbytes.
- DMA transaction setting modes

Register mode and link mode are supported.

- Register mode

In this mode, DMA transfer proceeds with the use of settings from the CPU. Up to two register sets (Next0 and Next1 register sets) can be set and alternating consecutive transfer according to the respective settings can proceed.

- Link mode

In this mode, the settings (descriptors) are allocated to the external memory and captured by the DMAC, after which DMA transfer proceeds in accord with the values. By preparing multiple settings which specify the addresses of the descriptors to control next transfers, sequential execution of transfers is possible. Additionally, suspension and resumption of the next DMA transfer can be specified by the header of the descriptor.

- Triggering modes

The following two types are supported to start DMA transfer.

- Software activation

DMA transfer is started by writing to an internal register.

- Hardware activation

DMA transfer is started according to the state of the DMAREQ input. The detection mode is selectable from those listed below. Masking is also possible.

- Rising-edge detection
- Falling-edge detection
- Change-point detection
- High-level detection
- Low-level detection

- Interrupt

Level and pulse interrupts are supported. In this LSI, use interrupts in level mode.

- Method of transfer

Transfer sizes for the source and the destination are individually selectable as values from among 1 to 128 bytes. For transfer addresses, increment mode and fixed mode are supported.

- Buffer flushing

Data already captured in the buffer can be forcibly flushed.

- Suspension

DMA transfer in progress can be suspended.

- Interval function

The interval between DMA transfers is specifiable to adjust the bus occupancy ratio.

### 19.1.2 DMA Transfer Specifications

- Maximum number of bytes for DMA transfer

Byte counting is specifiable per channel. The maximum number is  $(2^{32} - 1)$  bytes =  $(4G - 1)$  bytes.

### 19.1.3 Restrictions

If transfer proceeds with the use of this unit in such a way that the data source and destination areas are the same or parts of these areas overlap, data consistency cannot be guaranteed. Accordingly, make settings such that the data source and destination address areas do not overlap.

## 19.2 Connection Configuration

(Continuation of the previous page)

**[DMAC]**

**DMAC** — The DMA controller is made up of two main units.

**DMAC0:**

DMA Controller Main Unit 0 (eight channels are included and the number of buffer stages per channel is 16). DMA transfer control, arbitration control, DMA control registers, and DMA-dedicated interfaces are provided.

**DMAC1:**

DMA Controller Main Unit 1 (eight channels are included and the number of buffer stages per channel is 16). DMA transfer control, arbitration control, DMA control registers, and DMA-dedicated interfaces are provided.

**BUSIF:**

Interface section with the external bus.

The AXI master address width is 32 bits and the data bus width is 64 bits.

**ADRCNV** — Master address conversion section

Two bank switching address bits input by SYS are appended to the higher-order bits of the master address (MARADDR[31:0], MAWADDR[31:0]) for extension to a 34-bit address (MARADDR[33:0], MAWADDR[33:0]).

Figure 19.2-1 Connection Configuration

## 19.3 Pin Functions

### 19.3.1 List of Internal Pins

**Table 19.3-1** lists the internal pins of the DMAC.

Table 19.3-1 List of Internal Pins

| Pin Name                       | I/O    | Functions                                                                                                                                        |

| BANK_ADDR_DMACH{0,1}_DESC[1:0] | Input  | DMACH{0,1}, CH{0-7} bank switching address (for the descriptor)                                                                                  |

### 19.3.1.1 DMA Interfaces

Each DMAC can be set to select one request from among eight transfer requests by software.

The DMAREQ and DMAACK signals are referred to as the DMA signals and are on pins for use in hardware activation.

Eight DMAREQ and DMAACK signals are assigned to each DMAC unit. The bit positions to be used are switchable by using the SEL field of the DMAA\_DMAn\_CHCFG\_m register.

**Table 19.3-2** lists the destinations to which the DMAREQ and DMAACK pins of the DMAC unit are connected.

Table 19.3-2 DMAREQ and DMAACK Pin Assignment

| DMAC           |            | Connect To                                         |               |
|----------------|------------|----------------------------------------------------|---------------|
| DMAC Unit Name | Pin Name   | Unit Name                                          | Unit Pin Name |
| DMAC0          | DMAREQ[0]  | CSI0                                               | DMAREQTX      |
|                | DMAACK[0]  | CSI0                                               | DMAACKTX      |

|                | DMAACK[14] | No destination for connection (the output is open) | —             |
|                | DMAREQ[15] | UART1                                              | DMA_RX_REQ    |
|                | DMAACK[15] | No destination for connection (the output is open) | —             |

**DMAREQ (Input)**

This is a request input signal for DMA transfer.

Edge detection (rising-edge detection, falling-edge detection, and change-point detection) and level detection (high-level detection and low-level detection) are supported (masking requests is also possible).

Figure 19.3-1 DMAREQ Detection Mode

**DMAACK (Output)**

This is an acknowledge output signal for the DMAREQ signal.

This signal is activated in response to the start of transfer corresponding to the DMAREQ signal.

It supports pulse mode, level mode, and bus cycle mode (masking the output is also possible).

If the DMAACK signal is in level mode, it remains at the high level until the DMAREQ signal is deactivated.

A next DMA request is not accepted while the DMAACK signal is at the high level. Use this signal for handshaking with the DMAREQ signal.

The figure below shows the output modes of the respective DMAACK signals and the example timing charts.

Figure 19.3-2 DMAACK Signal Output

### 19.3.1.2 Interrupt Interfaces

#### DMAINT (Output)

This is a DMA transaction completed interrupt signal. This signal is asserted on the completion of the DMA transaction. It is also asserted when an invalid descriptor is read in link mode.

The DMAINT pins correspond to the DMAEND pins of the internal DMAC. **Table 19.3-3** shows the assignment of the channels of the DMAC units to the DMAINT pins.

Table 19.3-3 DMAINT Pin Assignment

| DMAINT pin | [15]  | [14] | [13] | [12] | [11] | [10] | [9] | [8] | [7]   | [6] | [5] | [4] | [3] | [2] | [1] | [0] |
|------------|-------|------|------|------|------|------|-----|-----|-------|-----|-----|-----|-----|-----|-----|-----|
| DMAC unit  | DMAC1 |      |      |      |      |      |     |     | DMAC0 |     |     |     |     |     |     |     |
| Channel    | 7     | 6    | 5    | 4    | 3    | 2    | 1   | 0   | 7     | 6   | 5   | 4   | 3   | 2   | 1   | 0   |

#### DMAERR (Output)

This is an error response (ERROR) interrupt signal. This signal is asserted when an error response is returned to the transfer request issued by the master interface. This pin is one bit and is common to all channels.

The format of this interrupt output is switchable between pulse output and level output through the setting of the register. After a reset, pulse output is selected.

#### CAUTION

Select level output in this product.

### 19.3.1.3 Bank Switching Addresses

There are three bank switching addresses for the source, destination, and descriptor per DMAC number and channel number.

These pins are associated with the AXI address conversion function. For details, see **Section 19.6.3, AXI Address Conversion**.

In this product, the SYS unit controls the corresponding pin by a register.

#### BANK\_ADDR\_DMACH{0,1}\_CH{0-7}\_SRC[1:0] (Input)

Bank switching address for CH{0-7} of DMAC{0,1} (for the source).

#### BANK\_ADDR\_DMACH{0,1}\_CH{0-7}\_DST[1:0] (Input)

Bank switching address for CH{0-7} of DMAC{0,1} (for the destination).

#### BANK\_ADDR\_DMACH{0,1}\_CH{0-7}\_DESC[1:0] (Input)

Bank switching address for CH{0-7} of DMAC{0,1} (for the descriptor).

# 19.4 Address Space

**Table 19.4-1** lists the allocation of the registers for DMAC0 and DMAC1.

Table 19.4-1 Address Space

| Address | Group               |
|---------|---------------------|
| 000h    | Registers for DMAC0 |
| :       |                     |
| 3FCh    |                     |
| 400h    | Registers for DMAC1 |
| :       |                     |
| 7FCh    |                     |

## 19.5 Register Descriptions

For the register base address (<DMAA\_S0\_base>), see the section of Address Map.

The following lists the registers of one DMAC unit.

### 19.5.1 List of Registers

**Table 19.5-1** lists the registers of the DMAC unit.

Table 19.5-1 List of Registers (1/7)

| Offset Address  | Group   | Register Name                          | Abbreviation        | Initial Value | Access Unit (bits) |
|-----------------|---------|----------------------------------------|---------------------|---------------|--------------------|
| DMAC0 Channel 0 |         |                                        |                     |               |                    |
| 000h            | Next0   | Next0 Source Address Register 0        | DMAA_DMAC0_N0SA_0   | 0000_0000h    | 32                 |

**CAUTION**

---

1. If the reserved area is accessed, an OK response is returned. The initial value and the read/write attribute of this area may be changed by the functional extension in the future. Do not write the code which expects that the value read from this area is 0b by software. When writing to it, write 0b.
  2. If the undefined area is accessed, an error response is returned. The control registers will not be changed.
  3. Do not modify the registers by software while DMA transfer is in progress (EN = 1b), with the exception of the following registers.
    - Register set on the side that has not transferred data in register mode
    - DMAA\_DMACn\_CHCTRL\_m
-

19.5.2 Register Descriptions

The functional description of each register is given below.

The prefix (DMAA\_DMAn\_) of the register names is omitted in the register descriptions and the field descriptions in this section.

The figure below shows the register configuration.

Figure 19.5-1 Register Configuration

**Next Register Set**

This register set sets the transfer source address, transfer destination address, and number of bytes to be transferred in the next DMA transaction to be executed.

It is composed of the Next0 and Next1 register sets.

In register mode, it is set by software. In link mode, the descriptor read data are automatically set in the Next0 register set.

The values of these register sets are loaded to the current register set and used for DMA transfer.

**Current Register Set**

This register set indicates the transfer source address, transfer destination address, and number of bytes being transferred in the DMA transaction that is currently in progress.

It is loaded from the Next0/1 register set (in register mode) or the descriptor read data (in link mode). It cannot be directly written by the user.

It is automatically updated every time the DMA transaction is executed.

**Channel Register Set**

This register set is used to make settings for DMA transfer.

It indicates the channel state, controls the channels, sets up DMA transactions, sets the interval between DMA transactions, and so on.

**Link Register Set**

This register set is composed of a register for setting the next descriptor address to be loaded (Next Link Address Register) and a register that indicates the descriptor address currently being executed (Current Link Address Register).

The Current Link Address Register is automatically updated by reading the descriptor and cannot be directly written by the user.

**DMA Register Set**

This register set is composed of a register that controls the entire DMAC and a register that indicates the state of the given channel. It is used to control the priority of channels, check the state of EN, ER, END, TCO, and SUS of the given channel, and so on.

19.5.2.1 Next0 Source Address Register m (DMAA\_DMAn\_N0SA\_m) (n = 1, 0, m = 7 to 0)

This register sets the DMA transfer source address (32 bits) of the DMAC channel m.

Access Size: 32 bits

Address(es): <DMAA\_S0\_base> + 0000h (n = 0, m = 0)  
<DMAA\_S0\_base> + 0040h (n = 0, m = 1)  
<DMAA\_S0\_base> + 0080h (n = 0, m = 2)  
<DMAA\_S0\_base> + 00C0h (n = 0, m = 3)  
<DMAA\_S0\_base> + 0100h (n = 0, m = 4)  
<DMAA\_S0\_base> + 0140h (n = 0, m = 5)  
<DMAA\_S0\_base> + 0180h (n = 0, m = 6)  
<DMAA\_S0\_base> + 01C0h (n = 0, m = 7)  
<DMAA\_S0\_base> + 0400h (n = 1, m = 0)  
<DMAA\_S0\_base> + 0440h (n = 1, m = 1)  
<DMAA\_S0\_base> + 0480h (n = 1, m = 2)  
<DMAA\_S0\_base> + 04C0h (n = 1, m = 3)  
<DMAA\_S0\_base> + 0500h (n = 1, m = 4)  
<DMAA\_S0\_base> + 0540h (n = 1, m = 5)  
<DMAA\_S0\_base> + 0580h (n = 1, m = 6)  
<DMAA\_S0\_base> + 05C0h (n = 1, m = 7)

Initial Value: 0000\_0000h

Table 19.5-2 DMAA\_DMAn\_N0SA\_m Register Contents

| Bit Position | Bit Name | Description                                                          |
|--------------|----------|----------------------------------------------------------------------|

19.5.2.2 Next0 Destination Address Register m (DMAA\_DMACn\_N0DA\_m) (n = 1, 0, m = 7 to 0)

This register sets the DMA transfer destination address (32 bits) of the DMAC channel m.

Access Size: 32 bits

Address(es): <DMAA\_S0\_base> + 0004h (n = 0, m = 0)  
<DMAA\_S0\_base> + 0044h (n = 0, m = 1)  
<DMAA\_S0\_base> + 0084h (n = 0, m = 2)  
<DMAA\_S0\_base> + 00C4h (n = 0, m = 3)  
<DMAA\_S0\_base> + 0104h (n = 0, m = 4)  
<DMAA\_S0\_base> + 0144h (n = 0, m = 5)  
<DMAA\_S0\_base> + 0184h (n = 0, m = 6)  
<DMAA\_S0\_base> + 01C4h (n = 0, m = 7)  
<DMAA\_S0\_base> + 0404h (n = 1, m = 0)  
<DMAA\_S0\_base> + 0444h (n = 1, m = 1)  
<DMAA\_S0\_base> + 0484h (n = 1, m = 2)  
<DMAA\_S0\_base> + 04C4h (n = 1, m = 3)  
<DMAA\_S0\_base> + 0504h (n = 1, m = 4)  
<DMAA\_S0\_base> + 0544h (n = 1, m = 5)  
<DMAA\_S0\_base> + 0584h (n = 1, m = 6)  
<DMAA\_S0\_base> + 05C4h (n = 1, m = 7)

Initial Value: 0000\_0000h

**CAUTION**

Treat transfers with the ER bit set as if the series of transfers is invalid. To interrupt a DMA transaction, mask and clear the transfer request or clear the enable. If a transfer request by DMA transfer request pin (DMAREQm) input and a transfer request by software (Set STG bit) are used together for the same channel, the activated activation factor cannot be specified. Use only one of the transfer requests in the system. When performing a transfer request by software, perform the next STG bit operation after completion(Check with Current Register etc.) of the previously requested DMA transfer operation.

### 19.5.2.11 Channel Control Register m (DMAA\_DMAn\_CHCTRL\_m) (n = 1, 0, m = 7 to 0)

This register controls the DMA transfer operation of DMA channel m.

**Access Size:** 32 bits

**Address(es):** <DMAA\_S0\_base> + 0028h (n = 0, m = 0)  
 <DMAA\_S0\_base> + 0068h (n = 0, m = 1)  
 <DMAA\_S0\_base> + 00A8h (n = 0, m = 2)  
 <DMAA\_S0\_base> + 00E8h (n = 0, m = 3)  
 <DMAA\_S0\_base> + 0128h (n = 0, m = 4)  
 <DMAA\_S0\_base> + 0168h (n = 0, m = 5)  
 <DMAA\_S0\_base> + 01A8h (n = 0, m = 6)  
 <DMAA\_S0\_base> + 01E8h (n = 0, m = 7)  
 <DMAA\_S0\_base> + 0428h (n = 1, m = 0)  
 <DMAA\_S0\_base> + 0468h (n = 1, m = 1)

When this bit is read, 0b can be read.<br>1b: Channel status register reset.<br>0b: Does not affect operation.                                                                    |
| 2            | STG      | Software Trigger<br>Setting this bit sets an internal transfer request (software activation). If it is set at the same time as the SWRST bit, clearing by the SWRST bit has priority. When this bit is read, 0b can be read.<br>1b: Set transfer request by software (set RQST bit).<br>0b: Does not affect operation. |
| 1            | CLREN    | Clear Enable<br>The EN bit can be cleared by setting this bit. When this bit is read, 0b can be read.<br>1b: DMA transfer stopped (EN bit cleared).<br>0b: Does not affect operation.                                                                                                                                  |
| 0            | SETEN    | Set Enable<br>Sets DMA transfer permission for DMAC channel m. If it is set at the same time as the SWRST bit, clearing by the SWRST bit has priority and transfer does not start. When this bit is read, 0b can be read.<br>1b: DMA transfer enabled (EN bit set).<br>0b: Does not affect operation.                  |

### 19.5.2.12 Channel Configuration Register m (DMAA\_DMACHCFG\_m) (n = 1, 0, m = 7 to 0)

This register controls the DMA transfer operation of DMA channel m.

**Access Size:** 32 bits

**Address(es):** <DMAA\_S0\_base> + 002Ch (n = 0, m = 0)  
 <DMAA\_S0\_base> + 006Ch (n = 0, m = 1)  
 <DMAA\_S0\_base> + 00ACh (n = 0, m = 2)  
 <DMAA\_S0\_base> + 00ECh (n = 0, m = 3)  
 <DMAA\_S0\_base> + 012Ch (n = 0, m = 4)  
 <DMAA\_S0\_base> + 016Ch (n = 0, m = 5)  
 <DMAA\_S0\_base> + 01ACh (n = 0, m = 6)  
 <DMAA\_S0\_base> + 01ECh (n = 0, m = 7)  
 <DMAA\_S0\_base> + 042Ch (n = 1, m = 0)  
 <DMAA\_S0\_base> + 046Ch (n = 1, m = 1)  
 <DMAA\_S0\_base> + 04ACh (n = 1, m = 2)  
 <DMAA\_S0\_base> + 04ECh (n = 1, m = 3)  
 <DMAA\_S0\_base> + 052Ch (n = 1, m = 4)  
 <DMAA\_S0\_base> + 056Ch (n = 1, m = 5)  
 <DMAA\_S0\_base> + 05ACh (n = 1, m = 6)  
 <DMAA\_S0\_base> + 05ECh (n = 1, m = 7)

## NOTE

If units with different clocks are DMA transfer targets and require DMAACK, the DMAACK signal may not be received successfully due to the synchronization clock. In such a case, set AM[2:0] to 001b or 010b so that DMAACK becomes active for a long time.

### 19.5.2.13 Channel Interval Register m (DMAA\_DMACHITVL\_m) (n = 1, 0, m = 7 to 0)

This register sets the transfer interval for DMAC channel m.

**Access Size:** 32 bits

**Address(es):** <DMAA\_S0\_base> + 0030h (n = 0, m = 0)  
 <DMAA\_S0\_base> + 0070h (n = 0, m = 1)  
 <DMAA\_S0\_base> + 00B0h (n = 0, m = 2)  
 <DMAA\_S0\_base> + 00F0h (n = 0, m = 3)  
 <DMAA\_S0\_base> + 0130h (n = 0, m = 4)  
 <DMAA\_S0\_base> + 0170h (n = 0, m = 5)  
 <DMAA\_S0\_base> + 01B0h (n = 0, m = 6)  
 <DMAA\_S0\_base> + 01F0h (n = 0, m = 7)  
 <DMAA\_S0\_base> + 0430h (n = 1, m = 0)  
 <DMAA\_S0\_base> + 0470h (n = 1, m = 1)  
 <DMAA\_S0\_base> + 04B0h (n = 1, m = 2)  
 <DMAA\_S0\_base> + 04F0h (n = 1, m = 3)  
 <DMAA\_S0\_base> + 0530h (n = 1, m = 4)  
 <DMAA\_S0\_base> + 0570h (n = 1, m = 5)  
 <DMAA\_S0\_base> + 05B0h (n = 1, m = 6)  
 <DMAA\_S0\_base> + 05F0h (n = 1, m = 7)

**Initial Value:** 0000\_0000h

Table 19.5-14 DMAA\_DMACHITVL\_m Register Contents

| Bit Position | Bit Name   | Description                                                               |
|--------------|------------|---------------------------------------------------------------------------|
| 31 to 16     | —          | Reserved. These bits are read as 0b. The write value should always be 0b. |
| 15 to 0      | ITVL[15:0] | Sets the channel transfer interval.                                       |

### 19.5.2.14 Channel Extension Register m (DMAA\_DMACn\_CHEXT\_m) (n = 1, 0, m = 7 to 0)

This register functions as the DMAC channel m expansion register.

**Access Size:** 32 bits

**Address(es):** <DMAA\_S0\_base> + 0034h (n = 0, m = 0)  
 <DMAA\_S0\_base> + 0074h (n = 0, m = 1)  
 <DMAA\_S0\_base> + 00B4h (n = 0, m = 2)  
 <DMAA\_S0\_base> + 00F4h (n = 0, m = 3)  
 <DMAA\_S0\_base> + 0134h (n = 0, m = 4)  
 <DMAA\_S0\_base> + 0174h (n = 0, m = 5)  
 <DMAA\_S0\_base> + 01B4h (n = 0, m = 6)  
 <DMAA\_S0\_base> + 01F4h (n = 0, m = 7)  
 <DMAA\_S0\_base> + 0434h (n = 1, m = 0)  
 <DMAA\_S0\_base> + 0474h (n = 1, m = 1)  
 <DMAA\_S0\_base> + 04B4h (n = 1, m = 2)  
 <DMAA\_S0\_base> + 04F4h (n = 1, m = 3)  
 <DMAA\_S0\_base> + 0534h (n = 1, m = 4)  
 <DMAA\_S0\_base> + 0574h (n = 1, m = 5)  
 <DMAA\_S0\_base> + 05B4h (n = 1, m = 6)  
 <DMAA\_S0\_base> + 05F4h (n = 1, m = 7)

**Initial Value:** 0000\_0000h

| 3            | —        | Reserved. This bit is read as 0b. The write value should always be 0b.                                         |
| 2 to 0       | SPR[2:0] | Destination PROT<br>Sets the output value to PROT[2:0] of DMA read transfer.<br>The initial value is 000b.     |

### 19.5.2.15 Next Link Address Register m (DMAA\_DMACn\_NXLA\_m) (n = 1, 0, m = 7 to 0)

This register sets the descriptor address to load next in link mode.

**Access Size:** 32 bits

**Address(es):** <DMAA\_S0\_base> + 0038h (n = 0, m = 0)  
 <DMAA\_S0\_base> + 0078h (n = 0, m = 1)  
 <DMAA\_S0\_base> + 00B8h (n = 0, m = 2)  
 <DMAA\_S0\_base> + 00F8h (n = 0, m = 3)  
 <DMAA\_S0\_base> + 0138h (n = 0, m = 4)  
 <DMAA\_S0\_base> + 0178h (n = 0, m = 5)  
 <DMAA\_S0\_base> + 01B8h (n = 0, m = 6)  
 <DMAA\_S0\_base> + 01F8h (n = 0, m = 7)  
 <DMAA\_S0\_base> + 0438h (n = 1, m = 0)  
 <DMAA\_S0\_base> + 0478h (n = 1, m = 1)  
 <DMAA\_S0\_base> + 04B8h (n = 1, m = 2)  
 <DMAA\_S0\_base> + 04F8h (n = 1, m = 3)  
 <DMAA\_S0\_base> + 0538h (n = 1, m = 4)  
 <DMAA\_S0\_base> + 0578h (n = 1, m = 5)  
 <DMAA\_S0\_base> + 05B8h (n = 1, m = 6)  
 <DMAA\_S0\_base> + 05F8h (n = 1, m = 7)

**Initial Value:** 0000\_0000h

Table 19.5-16 DMAA\_DMACn\_NXLA\_m Register Contents

| Bit Position | Bit Name   | Description                                                                                                    |
|--------------|------------|----------------------------------------------------------------------------------------------------------------|
| 31 to 0      | NXLA[31:0] | Set the link destination address. The lower 2 bits are masked with 0b. Only word-aligned addresses can be set. |

19.5.2.16 Current Link Address Register m (DMAA\_DMACn\_CRLA\_m) (n = 1, 0, m = 7 to 0)

This is a 32-bit register that displays the address of the currently executing descriptor.

Access Size: 32 bits

Address(es): <DMAA\_S0\_base> + 003Ch (n = 0, m = 0)  
<DMAA\_S0\_base> + 007Ch (n = 0, m = 1)  
<DMAA\_S0\_base> + 00BCh (n = 0, m = 2)  
<DMAA\_S0\_base> + 00FCh (n = 0, m = 3)  
<DMAA\_S0\_base> + 013Ch (n = 0, m = 4)  
<DMAA\_S0\_base> + 017Ch (n = 0, m = 5)  
<DMAA\_S0\_base> + 01BCh (n = 0, m = 6)  
<DMAA\_S0\_base> + 01FCh (n = 0, m = 7)  
<DMAA\_S0\_base> + 043Ch (n = 1, m = 0)  
<DMAA\_S0\_base> + 047Ch (n = 1, m = 1)  
<DMAA\_S0\_base> + 04BCh (n = 1, m = 2)  
<DMAA\_S0\_base> + 04FCh (n = 1, m = 3)  
<DMAA\_S0\_base> + 053Ch (n = 1, m = 4)  
<DMAA\_S0\_base> + 057Ch (n = 1, m = 5)  
<DMAA\_S0\_base> + 05BCh (n = 1, m = 6)  
<DMAA\_S0\_base> + 05FCh (n = 1, m = 7)

Initial Value: 0000\_0000h

Table 19.5-17 DMAA\_DMACn\_CRLA\_m Register Contents

| Bit Position | Bit Name   | Description                                                     |
|--------------|------------|-----------------------------------------------------------------|
| 31 to 0      | CRLA[31:0] | The address of the currently executing descriptor is displayed. |

### 19.5.2.17 DMA Control Register (DMAA\_DMACn\_DCTRL) (n = 1, 0)

This register sets the transfer type for descriptor access and arbitration between channels.

**Access Size:** 32 bits

**Address(es):** <DMAA\_S0\_base> + 0300h (n = 0)

<DMAA\_S0\_base> + 0700h (n = 1)

**Initial Value:** 0000\_0000h

| 19           | —         | Reserved. This bit is read as 0b. The write value should always be 0b.                                                                                                         |
| 18 to 16     | LDPR[2:0] | Link Descriptor PROT<br>Sets the value to be output to MHPROT[2:0] when loading a descriptor in link mode.                                                                     |
| 15 to 2      | —         | Reserved. This bit is read as 0b. The write value should always be 0b.                                                                                                         |
| 1            | LVINT     | Sets whether to output DMAEND[7:0], DMAERR as a pulse or level.<br>0b: Pulse output (initial value)<br>1b: Level output<br><br><i>Note:</i> Pulse output setting is prohibited |
| 0            | PR        | Sets the transfer priority control mode between channels<br>0b: Fixed priority mode (initial value)<br>1b: Round robin mode                                                    |

**19.5.2.18 DMA Status EN Register (DMAA\_DMACn\_DST\_EN) (n = 1, 0)**

This register displays the EN bit status of all channels.

Writing to this register does not change the value of each bit.

**Access Size:** 32 bits

**Address(es):** <DMAA\_S0\_base> + 0310h (n = 0)

<DMAA\_S0\_base> + 0710h (n = 1)

**Initial Value:** 0000\_0000h

Table 19.5-19 DMAA\_DMACn\_DST\_EN Register Contents

| Bit Position | Bit Name | Description                                      |
|--------------|----------|--------------------------------------------------|
| 31 to 8      | —        | Reserved. These bits are read as 0b.             |
| 7            | EN7      | Displays the state of the DMAC channel 7 EN bit. |
| 6            | EN6      | Displays the state of the DMAC channel 6 EN bit. |
| 5            | EN5      | Displays the state of the DMAC channel 5 EN bit. |
| 4            | EN4      | Displays the state of the DMAC channel 4 EN bit. |
| 3            | EN3      | Displays the state of the DMAC channel 3 EN bit. |
| 2            | EN2      | Displays the state of the DMAC channel 2 EN bit. |
| 1            | EN1      | Displays the state of the DMAC channel 1 EN bit. |
| 0            | EN0      | Displays the state of the DMAC channel 0 EN bit. |

**NOTE**

Channels that do not exist in the channel configuration are set to 0b.

**19.5.2.19 DMA Status ER Register (DMAA\_DMACn\_DST\_ER) (n = 1, 0)**

Displays the ER bit status of all channels.

Writing to this register does not change the value of each bit.

**Access Size:** 32 bits

**Address(es):** <DMAA\_S0\_base> + 0314h (n = 0)

<DMAA\_S0\_base> + 0714h (n = 1)

**Initial Value:** 0000\_0000h

Table 19.5-20 DMAA\_DMACn\_DST\_ER Register Contents

| Bit Position | Bit Name | Description                                      |
|--------------|----------|--------------------------------------------------|
| 31 to 8      | —        | Reserved. These bits are read as 0b.             |
| 7            | ER7      | Displays the state of the DMAC channel 7 ER bit. |
| 6            | ER6      | Displays the state of the DMAC channel 6 ER bit. |
| 5            | ER5      | Displays the state of the DMAC channel 5 ER bit. |
| 4            | ER4      | Displays the state of the DMAC channel 4 ER bit. |
| 3            | ER3      | Displays the state of the DMAC channel 3 ER bit. |
| 2            | ER2      | Displays the state of the DMAC channel 2 ER bit. |
| 1            | ER1      | Displays the state of the DMAC channel 1 ER bit. |
| 0            | ER0      | Displays the state of the DMAC channel 0 ER bit. |

**NOTE**

Channels that do not exist in the channel configuration are set to 0b.

**19.5.2.20 DMA Status END Register (DMAA\_DMACn\_DST\_END) (n = 1, 0)**

This register displays the END bit status of all channels.

Writing to this register does not change the value of each bit.

**Access Size:** 32 bits

**Address(es):** <DMAA\_S0\_base> + 0318h (n = 0)

<DMAA\_S0\_base> + 0718h (n = 1)

**Initial Value:** 0000\_0000h

Table 19.5-21 DMAA\_DMACn\_DST\_END Register Contents

| Bit Position | Bit Name | Description                                       |
|--------------|----------|---------------------------------------------------|
| 31 to 8      | —        | Reserved. These bits are read as 0b.              |
| 7            | END7     | Displays the state of the DMAC channel 7 END bit. |
| 6            | END6     | Displays the state of the DMAC channel 6 END bit. |
| 5            | END5     | Displays the state of the DMAC channel 5 END bit. |
| 4            | END4     | Displays the state of the DMAC channel 4 END bit. |
| 3            | END3     | Displays the state of the DMAC channel 3 END bit. |
| 2            | END2     | Displays the state of the DMAC channel 2 END bit. |
| 1            | END1     | Displays the state of the DMAC channel 1 END bit. |
| 0            | END0     | Displays the state of the DMAC channel 0 END bit. |

**NOTE**

Channels that do not exist in the channel configuration are set to 0b.

**19.5.2.21 DMA Status TC Register (DMAA\_DMAn\_DST\_TC) (n = 1, 0)**

This register displays the TC bit status of all channels.

Writing to this register does not change the value of each bit.

**Access Size:** 32 bits

**Address(es):** <DMAA\_S0\_base> + 031Ch (n = 0)

<DMAA\_S0\_base> + 071Ch (n = 1)

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

Table 19.5-22 DMAA\_DMAn\_DST\_TC Register Contents

| Bit Position | Bit Name | Description                                      |
|--------------|----------|--------------------------------------------------|
| 31 to 8      | —        | Reserved. These bits are read as 0b.             |
| 7            | TC7      | Displays the state of the DMAC channel 7 TC bit. |
| 6            | TC6      | Displays the state of the DMAC channel 6 TC bit. |
| 5            | TC5      | Displays the state of the DMAC channel 5 TC bit. |
| 4            | TC4      | Displays the state of the DMAC channel 4 TC bit. |
| 3            | TC3      | Displays the state of the DMAC channel 3 TC bit. |
| 2            | TC2      | Displays the state of the DMAC channel 2 TC bit. |
| 1            | TC1      | Displays the state of the DMAC channel 1 TC bit. |
| 0            | TC0      | Displays the state of the DMAC channel 0 TC bit. |

**NOTE**

Channels that do not exist in the channel configuration are set to 0b.

**19.5.2.22 DMA Status SUS Register (DMAA\_DMACn\_DST\_SUS) (n = 1, 0)**

This register displays the SUS bit status of all channels.

Writing to this register does not change the value of each bit.

**Access Size:** 32 bits

**Address(es):** <DMAA\_S0\_base> + 0320h (n = 0)

<DMAA\_S0\_base> + 0720h (n = 1)

**Initial Value:** 0000\_0000h

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Table 19.5-23 DMAA\_DMACn\_DST\_SUS Register Contents

| Bit Position | Bit Name | Description                                       |
|--------------|----------|---------------------------------------------------|
| 31 to 8      | —        | Reserved. These bits are read as 0b.              |
| 7            | SUS7     | Displays the state of the DMAC channel 7 SUS bit. |
| 6            | SUS6     | Displays the state of the DMAC channel 6 SUS bit. |
| 5            | SUS5     | Displays the state of the DMAC channel 5 SUS bit. |
| 4            | SUS4     | Displays the state of the DMAC channel 4 SUS bit. |
| 3            | SUS3     | Displays the state of the DMAC channel 3 SUS bit. |
| 2            | SUS2     | Displays the state of the DMAC channel 2 SUS bit. |
| 1            | SUS1     | Displays the state of the DMAC channel 1 SUS bit. |
| 0            | SUS0     | Displays the state of the DMAC channel 0 SUS bit. |

**NOTE**

Channels that do not exist in the channel configuration are set to 0b.

## 19.6 Functional Description

The prefix (DMAA\_DMACn\_) of the register names is omitted in this and subsequent sections.

### 19.6.1 DMA Mode

This section describes the DMAC mode specifications of the DMAC unit.

#### 19.6.1.1 Mode Setting

The DMA mode can be switched between register mode and link mode according to the value of the DMS field in the CHCFG\_m register.

Table 19.6-1 DMA Mode Setting

| DMS<br>(CHCFG_m) | Mode          | Description                                                                                                                                                                                                                 |
|------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0b               | Register mode | The values set in the next register set are used to proceed with DMA transfer.                                                                                                                                              |
| 1b               | Link mode     | The descriptor is set in the current register to proceed with DMA transfer. Loading of the descriptor and DMA transfer are repeated unless these are stopped with the setting by the descriptor or by the control register. |

### 19.6.1.2 Register Mode

In register mode, the values set in the internal registers are used for DMA transfer.

Two types (Next0 Register Set and Next1 Register Set) of transfer source address, transfer destination address, and number of transfer bytes can be set. The Next register set to be used can be selected and transferred, or two Next register sets can be transferred consecutively.

Figure 19.6-1 Overview of Register Normal Mode

The above figure illustrates operations when Next0 is executed (upper part of the figure) and when Next1 is executed (lower part of the figure).

## (1) Flow of Operations

Figure 19.6-2 Register Mode Flow

**<Description of the Register Mode Flow>****1. Set channel configuration**

In addition, set the DMA register set (REQ, DMAACK, the amount of data for transfer, etc.) in the channel register set (See **Section 19.6.2, DMA Transfer**).

**2. Register set selection**

When the EN bit is set to 1b, the setting of the next register set selected by RSEL is loaded to the current register set.

**3. Processing DMA transaction**

DMA transfer proceeds in accord with the set value. For details of transfer, see **Section 19.6.2, DMA Transfer**.

**4. Masking DMAEND**

DMAEND is masked in accord with the value set in the DEM bit of CHCFG\_m. DMAEND is not output if DEM = 1b. After that, DEM is automatically cleared to 0b.

**5. Register set automatic change**

Whether or not the other next register set is to be used is determined by the value set in the RSW bit of CHCFG\_m.

**6. Continuous execution**

Whether or not DMA transfer is to be consecutively executed is determined by the value set in the REN bit of CHCFG\_m. Transfer is executed consecutively if REN = 1b. After that, REN is automatically cleared to 0b.

## (2) Register Settings

### (a) Register Mode Setting

Select the register set to be executed.

Table 19.6-2 Register Mode Setting

| DMS<br>(CHCFG_m) | RSEL<br>(CHCFG_m) | Description                     |
|------------------|-------------------|---------------------------------|
| 0b               | 0b                | Execute the Next0 register set. |
|                  | 1b                | Execute the Next1 register set. |

### (b) DMAEND Mask Setting

DMAEND can be masked for each register set.

Table 19.6-3 DMAEND Mask Setting

| DEM<br>(CHCFG_m) | Operation                                                                                                                                            | Remarks |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 0b               | DMAEND is issued on completion of the DMA transaction.                                                                                               |         |
| 1b               | DMAEND is not issued even if the DMA transaction has completed.<br>DEM is cleared to 0b by hardware following the completion of the DMA transaction. |         |

### (c) Automatic Register Set Execution Setting

After DMA transfer, a DMA transaction of the selected register set is automatically executed.

Table 19.6-4 Automatic Register Set Execution Setting

| REN<br>(CHCFG_m) | Operation                                                                                                                                                                      | Remarks                                                             |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|
| 0b               | When the DMA transaction of the register set that is set in the RSEL bit is completed, the EN bit is cleared to end DMA operation.                                             | Set this to execute the DMA transaction once.                       |
| 1b               | After the completion of the DMA transaction, DMA transfer of the contents of the selected register set follows. When continuous transfer is established, REN is cleared to 0b. | Set this to execute the contents of the register set consecutively. |

### (d) Automatic Register Set Execution Setting

When REN = 1b, the next register set to be automatically executed can be switched following the completion of the DMA transaction.

Table 19.6-5 Automatic Register Set Execution Setting

| RSW<br>(CHCFG_m) | Operation                                                                                                                  | Remarks                                    |
|------------------|----------------------------------------------------------------------------------------------------------------------------|--------------------------------------------|
| 0b               | When REN = 1b and the DMA transaction is completed, the register set is not switched.                                      | Set this when using one register set only. |
| 1b               | When REN = 1b and the DMA transaction is completed, RSEL is automatically inverted and the other register set is selected. | Set this when switching the register set.  |

(3) Example Settings

(a) When Using the Next0 Register Set Only

Table 19.6-6 Example Register Mode Setting 1

| DMS<br>(CHCFG_m)      | RSEL<br>(CHCFG_m) | DEM<br>(CHCFG_m)   | TCM<br>(CHCFG_m)   | RSW<br>(CHCFG_m)     | REN<br>(CHCFG_m)                |
|-----------------------|-------------------|--------------------|--------------------|----------------------|---------------------------------|
| 0b<br>(Register mode) | 0b<br>(Next0)     | 0b<br>(No masking) | 0b<br>(No masking) | 0b<br>(No switching) | 0b<br>(No continuous execution) |

Figure 19.6-3 Example Register Mode Setting 1

1. Set EN = 1b (SETEN = 1b) to load the Next0 register set to the current register set.
2. Execute a DMA transaction according to the values of the current register set and channel register set.
3. DMAEND is issued following the completion of the DMA transaction.
4. Since REN is 0b, clear EN to 0b to end the operation.

**(b) When Using Two Register Sets Consecutively**

Table 19.6-7 Automatic Register Set Execution Setting

| DMS<br>(CHCFG_m)      | RSEL<br>(CHCFG_m) | DEM<br>(CHCFG_m) | TCM<br>(CHCFG_m)   | RSW<br>(CHCFG_m)  | REN<br>(CHCFG_m)             |
|-----------------------|-------------------|------------------|--------------------|-------------------|------------------------------|
| 0b<br>(Register mode) | 0b<br>(Next0)     | 1b<br>(Masking)  | 0b<br>(No masking) | 1b<br>(Switching) | 1b<br>(Continuous execution) |

Figure 19.6-4 Example Register Mode Setting 2

1. Set EN = 1b (SETEN = 1b) to load the Next0 register set to the current register set.
2. Execute a DMA transaction according to the values of the current register set and channel register set.
3. Since DEM is 1b, DMAEND is not output following the completion of the DMA transaction. DEM is automatically cleared to 0.
4. Since REN is 1b, the operation is executed continuously. REN is automatically cleared to 0b.
5. Since RSW is 1b, the next register set to be executed is switched (RSEL = 0b → 1b).
6. Load the Next1 register set to the current register set.
7. Execute a DMA transaction according to the values of the current register set and channel register set.
8. Since DEM is 0b, DMAEND is issued following the completion of the DMA transaction.
9. Since REN is 0b, clear EN to 0b to end the operation.

19.6.1.3 Link Mode

In link mode, a DMA transaction is executed by loading descriptors in the external memory area as the settings. The DMAC has a next link address and current link address per channel and these are used to set the address of a next descriptor to be executed and to indicate the address of a descriptor for the DMA transaction that is currently in progress, respectively.

Figure 19.6-5 Overview of Link Mode

## (1) Flow of Operations

Figure 19.6-6 Flow of Link Mode

**<Description of the Link Mode Flow>****1. Set channel configuration**

Set the address where the link destination is to start in NXLA\_m.

**2. Link address update**

Setting EN = 1b (setting SETEN to 1b) loads the link address set in NXLA\_m to CRLA\_n.

**3. Reading the descriptor and judging the header**

The DMAC starts to load the descriptor and checks the header contents. If LV = 0b, the descriptor is discarded and DER is set to 1b indicating the end state (EN = 0b). If DIM within the header is 0b at this time, DMAEND is issued.

**4. Descriptor setting**

Set the loaded descriptor in the current register set and channel register set. Also, set the next link destination in NXLA\_m.

**5. Processing DMA transaction**

Execute a DMA transaction according to the set values.

**6. Header write-back**

If WBD in the header = 0b, the DMAC writes back 0b to the LV bit in the header.

**7. Masking DMAEND**

If the DEM bit in CHCFG\_m is 0b, DMAEND is issued.

**8. Judging the end of the link**

If LE in the header = 1b, after the transfer according to the descriptor settings, TCO is issued (enabling masking by CHCFG\_m) and EN is cleared to 0b to stop the operation. If LE = 0b, the current register set is updated and the DMAC starts to load the next descriptor.

## (2) Register Settings

### (a) Link Mode Setting

To use link mode, set the DMS bit in the CHCFG\_m register to 1b.

Table 19.6-8 Link Mode Setting

| DMS<br>(CHCFG_m) | Description                                                                              |
|------------------|------------------------------------------------------------------------------------------|
| 1b               | Operation is in link mode.<br>The value of this bit cannot be changed by the descriptor. |

### (b) LINK Address Setting

There are the next link address register and the current link address register as registers which indicate the link destination.

When starting link mode, set the link destination in the next link address register.

The next link address indicates the next link destination after loading of the descriptor. The current link address indicates the address of the link currently being executed.

Table 19.6-9 Link Address Register Set

| Register                                  | Description                                                                                                                        |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| Next Link Address Register<br>(NXLA_m)    | Sets and indicates the next link destination. Before starting link mode, set the address of the link destination in this register. |
| Current Link Address Register<br>(CRLA_n) | Indicates the link destination currently being executed. This register is only readable.                                           |

## CAUTION

In link mode, the setting can be changed by reading the descriptor; however the timing of the change to the setting and a hardware request cannot be synchronized. Therefore, when using hardware requests, set AM, LVL, HIEN, LOEN, and SEL of the CHCFG\_m register before enabling hardware requests and also make sure that these setting bits have the same values in the descriptor.

(3) Descriptor Settings

From the link destination address, prepare the parts of each descriptor in the following order.  
The DMAC reads the descriptors in bursts.

(a) Descriptor Arrangement

Table 19.6-10 Descriptor Setting Arrangement

| Address           | Data                | Remark                       |
|-------------------|---------------------|------------------------------|
| LinkAddress + 00h | Header              |                              |
| LinkAddress + 04h | Source address      |                              |
| LinkAddress + 08h | Destination address |                              |
| LinkAddress + 0Ch | Transaction byte    |                              |
| LinkAddress + 10h | Config              | Register mode cannot be set. |
| LinkAddress + 14h | Interval            |                              |
| LinkAddress + 18h | Extension           |                              |
| LinkAddress + 1Ch | Next link address   |                              |

**Note:** For the link destination, set the addresses aligned in 32-bit boundaries.

(b) Header

The header indicates the descriptor state as shown below.  
This area is automatically read by the DMAC before starting DMA transfer in link mode. After the completion of the DMA transaction, the DMAC writes back the header and sets the LV bit to 0b to indicate the state of transfer.

Figure 19.6-7 Header Area

Table 19.6-11 Header Area

| Bit Position | Bit Name | Function                                                                                                                                                                                                                                                                                                      |
|--------------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:4         | —        | —                                                                                                                                                                                                                                                                                                             |
| 3            | DIM      | Descriptor Interrupt Mask<br>If LV = 0b when the header is loaded, this bit sets whether or not to mask DMAEND.<br>0b: DMAEND is issued.<br>1b: DMAEND is not issued.                                                                                                                                         |
| 2            | WBD      | Write Back Disable<br>This bit masks execution of write-back to the LV bit. When the setting of this bit is 1b, the DMAC does not proceed with write-back operation.<br>0b: The LV bit is written back to 0.<br>1b: The LV bit is not written back.                                                           |
| 1            | LE       | Link End<br>This bit indicates that the link ends in the DMA transaction of this descriptor.<br>Set this bit to 1b to indicate the end of the link.<br>0b: The link continues.<br>1b: The link ends.                                                                                                          |
| 0            | LV       | Link Valid<br>This bit indicates that this descriptor is enabled.<br>When WBD = 0b, the DMAC writes 0b to this bit following the execution of the DMA transaction written in the descriptor. When setting the header, set this bit to 1b.<br>0b: The descriptor is disabled.<br>1b: The descriptor is enabled |

### (c) Setting the Descriptors Other than the Header

The values in the descriptors other than the header have the same specifications as those of the internal registers (however, the DMS bit of the CHCFG\_m register cannot be modified by the descriptor). For the specifications of the internal registers, see **Section 19.5, Register Descriptions**.

For example settings of the descriptors, see **Section 19.7.1.4, Example Setting 4 (Link Mode)**.

### (d) PROT and CACHE Settings at the Time of Access to the Descriptors

The PROT and CACHE settings at the time of access to the descriptors can be set in LWCA, LWPR, LDCA, and LDPR described in **Section 19.5.2.17, DMA Control Register (DMAA\_DMACn\_DCTRL) (n = 1, 0)**. Make the settings according to the destination for access in which the descriptors are prepared.

**(e) Descriptor Areas and DMA Transfer Areas**

The figure below shows an overview of the descriptor areas and DMA transfer areas, which are accessed by the DMAC.

Figure 19.6-8 Overview of the Descriptor Areas and DMA Transfer Areas

**(1) Descriptor read**

Load the value set in the internal next link address register to the current link address register, and then read the descriptor from the external memory space (descriptor 1) indicated by the current link address register.

**(2) DMA transfer**

If LV in the header of the descriptor = 1b, execute DMA transfer according to the descriptor information.

**(3) Descriptor write-back**

After the DMA transfer for the specified number of bytes, if WBD in the header = 0b, write-back is executed on the header of descriptor 1 in the burst size of 32 bits with 0b for LV and the value read in step 1 for the other fields as data.

(4) Descriptor read

If LE in the header of the descriptor which has been previously read (in step 1) = 0b, read the next descriptor from the address (descriptor 2) indicated by the next link address in the descriptor.

(5) DMA transfer

If LV in the header of the descriptor = 1b, execute DMA transfer according to the descriptor information.

(6) Descriptor write-back

After the DMA transfer for the specified number of bytes, if WBD in the header = 0b, write-back is executed on the header of descriptor 2 in the burst size of 32 bits with 0 for LV and the value read in step 4 for the other fields as data.

After that, repeat steps (4) to (6).

If LE in the header = 1b and WBD = 0b, DMA transfer proceeds in accord with the descriptor settings, and 0 is written back to the LV bit of the header, after which the operation ends.

If LE in the header = 1b and WBD = 1b, DMA transfer proceeds in accord with the descriptor settings, after which the operation ends (write-back does not proceed).

If LV in the header = 0b, the operation stops (DMA transfer does not proceed).

#### (4) Example Descriptor Configuration

In link mode, descriptors can be configured as shown in the figure below.

Figure 19.6-9 Example Descriptor Configuration

- List configuration

Setting the LE bit in the header of the last descriptor to 1b ends the link.

- Loop configuration

Setting the address of the first descriptor as the link address for the last descriptor configures the descriptors in a loop. To end the loop, either overwrite the LE bit of the header with 1b before the DMAC reads the descriptor or stop the DMAC according to the transfer suspension procedure.

## 19.6.2 DMA Transfer

This section describes basic operations of DMA transfer by the DMAC unit.

### 19.6.2.1 Transfer Mode

As the transfer mode, single-transfer mode and block-transfer mode are supported.

Select the mode by using the TM bit of CHCFG\_m per channel.

Use single-transfer mode for normal DMA transfer with the use of the DMAREQm input and block-transfer mode for memory-to-memory transfer, etc., with the use of software activation.

Table 19.6-12 Basic Transfer Setting

| Transfer Mode   | TM<br>(CHCFG_m) | Function                                                                                                   | Usage                                                                            |
|-----------------|-----------------|------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| Single transfer | 0b              | A single round of DMA transfer proceeds in response to a single DMAREQ.                                    | Use this mode for DMA transfer with the use of the DMAREQ input.                 |
| Block transfer  | 1b              | Transfer proceeds in response to a single software activation until the completion of the DMA transaction. | Use this mode for memory-to-memory transfer with the use of software activation. |

#### (1) Single-Transfer Mode

When a DMA transfer request is received, DMA transfer is executed once in the direction (source or destination) indicated by REQD and DMAACK is asserted. A single round of transfer proceeds every time a transfer request is received and this operation is repeated for the number of bytes loaded to CRTB\_m (arbitration between channels proceeds per DMA transfer).

The timing of DMAACK and the timing of counting CRTB vary with the setting of REQD and the transfer size (DDS, SDS). For details, see **Section 19.6.2.8, Differences in Operation with the Transfer Size**.

Figure 19.6-10 Single-Transfer Mode (REQD = 1b, SDS > DDS)

(2) Block-Transfer Mode

Once a DMA transfer request is received, transfer continues until a transfer for the number of bytes loaded to the DMA transfer byte register (CRTB\_m register) is completed (the completion of the DMA transaction) (arbitration between channels proceeds per DMA transfer).

Figure 19.6-11 Block-Transfer Mode (REQD = 0b, SDS < DDS)

### 19.6.2.2 Control Over the Priority of DMAC Channels

Fixed priority mode and round-robin mode are supported as the order of priority among channels 0 to 7 of DMAC0 and among channels 0 to 7 of DMAC1. The mode is selected by using the PR bit of the DMA control register (DCTRL). When the setting of the PR bit is 0b, operation is in fixed priority mode; when it is 1b, operation is in round-robin mode.

Table 19.6-13 Priority Control Setting

| Mode           | PR (DCTRL) | Function                                                                                                  | Usage                                                |
|----------------|------------|-----------------------------------------------------------------------------------------------------------|------------------------------------------------------|
| Fixed priority | 0b         | Controls requests in the fixed priority order (high: CH0 > CH1 > CH2 > CH3 > CH4 > CH5 > CH6 > CH7: low). | Use this mode when channels have the priority order. |
| Round-robin    | 1b         | Controls requests in round-robin fashion.                                                                 | Use this mode to execute each request evenly.        |

Round-robin mode is only supported as the order of priority between DMAC0 and DMAC1. In round-robin mode, the DMAC of DMAC no (which is currently executing transfer) + 1 has the highest priority. After a reset, DMAC0 is given the highest priority.

Table 19.6-14 Priority of Transfer Requests for DMAC during Transfer

| Current DMAC \ Next DMAC | DMAC0 | DMAC1 |
|--------------------------|-------|-------|
| DMAC0                    | 2     | 1     |
| DMAC1                    | 1     | 2     |

**Note:** Priority: 1 (high) ⇔ 2 (low)

The priority of reading and that of writing are controlled independently.

The DMAC issues transfer requests to the individual channels concurrently without waiting for the completion of transfer and handles them in the order the responses are returned. Therefore, the orders in which transactions start and end do not necessarily match.

#### (1) Fixed Priority Mode

In fixed priority mode, the order of priority among channels 0 to 7 of DMAC0 and among channels 0 to 7 of DMAC1 is fixed. The order of priority between DMAC0 and DMAC1 is round-robin. The order of priority after a reset is as follows.

High D0\_CH0 > D1\_CH0 > D0\_CH1 > D1\_CH1 > D0\_CH2 > D1\_CH2 > D0\_CH3 > D1\_CH3 > D0\_CH4 > D1\_CH4 > D0\_CH5 > D1\_CH5 > D0\_CH6 > D1\_CH6 > D0\_CH7 > D1\_CH7 Low

**Note:** D0 and D1 refer to DMAC0 and DMAC1, respectively.

If a transfer request for channel 0 of DMAC0 is output in this state, transfer by channel 0 of DMAC0 proceeds. The order of priority after the end of transfer is as follows.

High D1\_CH1 > D0\_CH0 > D1\_CH1 > D0\_CH1 > D1\_CH2 > D0\_CH2 > D1\_CH3 > D0\_CH3 > D1\_CH4 >  
D0\_CH4 > D1\_CH5 > D0\_CH5 > D1\_CH6 > D0\_CH6 > D1\_CH7 > D0\_CH7 Low

Note: D0 and D1 refer to DMAC0 and DMAC1, respectively.

If DMA transfer requests are generated on multiple channels simultaneously, the request for a smaller number channel is given priority. The figure below shows an example when another DMA transfer request with higher priority is generated while DMA transfer proceeds in fixed priority mode.

## (2) Round-Robin Mode

In round-robin mode, the order of priority is changed so that the channel which has proceeded with the immediately preceding transfer is given the lowest priority every time a transfer among channels 0 to 7 of DMAC0 and among channels 0 to 7 of DMAC1 is accepted.

The order of priority between DMAC0 and DMAC1 is also determined in round-robin.

As with fixed priority mode, the order of priority after a reset is as follows.

High D0\_CH0 > D1\_CH0 > D0\_CH1 > D1\_CH1 > D0\_CH2 > D1\_CH2 > D0\_CH3 > D1\_CH3 > D0\_CH4 >  
D1\_CH4 > D0\_CH5 > D1\_CH5 > D0\_CH6 > D1\_CH6 > D0\_CH7 > D1\_CH7 Low

Note: D0 and D1 refer to DMAC0 and DMAC1, respectively.

If a transfer request for channel 2 of DMAC0 is output in this state, transfer by channel 2 of DMAC0 proceeds. The order of priority after the end of transfer is as follows.

High D1\_CH0 > D0\_CH3 > D1\_CH1 > D0\_CH4 > D1\_CH2 > D0\_CH5 > D1\_CH3 > D0\_CH6 > D1\_CH4 > D0\_CH7  
> D1\_CH5 > D0\_CH0 > D1\_CH6 > D0\_CH1 > D1\_CH7 > D0\_CH2 Low

Note: D0 and D1 refer to DMAC0 and DMAC1, respectively.

### 19.6.2.3 DMA Transfer Request

Edge detection or level detection is selectable by using the LVL bit of the CHCFG\_m register.

The HIEN and LOEN bits of the CHCFG\_m register are used to select rising or falling edge for edge detection and the high or low level for level detection.

Table 19.6-15 DMAREQ Pin Selection Setting

| SEL[2:0]<br>(CHCFG_m) | Request Pin | Acknowledge Pin | Usage                                      |
|-----------------------|-------------|-----------------|--------------------------------------------|
| 000b                  | DMAREQ[0]   | DMAACK[0]       | Set the DMAC pin to be used for channel n. |
| 001b                  | DMAREQ[1]   | DMAACK[1]       |                                            |
| 010b                  | DMAREQ[2]   | DMAACK[2]       |                                            |
| 011b                  | DMAREQ[3]   | DMAACK[3]       |                                            |
| 100b                  | DMAREQ[4]   | DMAACK[4]       |                                            |
| 101b                  | DMAREQ[5]   | DMAACK[5]       |                                            |
| 110b                  | DMAREQ[6]   | DMAACK[6]       |                                            |
| 111b                  | DMAREQ[7]   | DMAACK[7]       |                                            |

Table 19.6-16 DMAREQ Detection Setting

| Mode               | LVL<br>(CHCFG_m) | HIEN<br>(CHCFG_m) | LOEN<br>(CHCFG_m) | Function                                                                                                                                                                                                                                                  | Usage                                                                         |
|--------------------|------------------|-------------------|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------|

|                    |                  |                   | 1b                | Detection of rising and falling edges of DMAREQm.                                                                                                                                                                                                         |                                                                               |
| Level<br>detection | 1b               | 0b                | 0b                | Level detection cannot be performed in this setting.                                                                                                                                                                                                      |                                                                               |
|                    |                  |                   | 1b                | DMAREQm is detected in the low-level mode.                                                                                                                                                                                                                |                                                                               |
|                    |                  | 1b                | 0b                | DMAREQm is detected in high-level mode.                                                                                                                                                                                                                   |                                                                               |
|                    |                  |                   | 1b                | Transfer starts in response to the SETEN bit of the CHCTRL_m register being set to 1b regardless of the input level of DMAREQm.<br>In this setting, set DMAACK to the mode other than level mode. If level mode is set, the operation will be deadlocked. |                                                                               |

#### CAUTION

- For the setting for detection of DMAREQ, make the setting to suit the system.
- Make the setting for DMAREQ independently of the setting for DMAACK.

### (1) Edge Detection

Edge detection is selected by setting the LVL bit in the CHCFG\_m register.

Setting the HIEN bit of the CHCFG\_m register to 1 selects rising-edge detection and setting the LOEN bit to 1 selects falling-edge detection.

Make sure that the unit to be connected issues a next DMA transfer request after waiting for detection of DMAACK.

Figure 19.6-12 Edge Detection Timing (HIEN = 1b, REQD = 0b)

Figure 19.6-13 Edge Detection Timing (HIEN = 1b, REQD = 1b)

## (2) Level Detection

Setting the LVL bit of the CHCFG\_m register to 1 selects level detection.

If DMAREQ is at the active level (by the setting of HIEN or LOEN) for at least two consecutive clock cycles, it is recognized as a correct DMAREQ.

If DMAACK is set to level mode, DMAACK is at the high level until DMAREQ is de-asserted, so when a next DMA transfer request is to be output, assert DMAREQ after waiting for DMAACK to be de-asserted.

Figure 19.6-14 Level Detection Timing (HIEN = 1b, REQD = 0b, AM[2:0] = 001b)

Figure 19.6-15 Level Detection Timing (HIEN = 1b, REQD = 1b, AM[2:0] = 001b)

#### 19.6.2.4 DMA Acknowledge Output

DMAACK[7:0] is an acknowledge signal for the request source that outputs a DMA transfer request. This unit supports pulse output, level output, and bus cycle output to output DMAACK.

The SEL bit of the CHCFG\_m register is used to select one from among the eight DMAACK[7:0] outputs per channel (See **Table 19.6-15**).

##### (1) DMA Acknowledge Signal Output Timing Setting

When the DMA transfer request is accepted, the acknowledge signal becomes active level (high level output). The REQD and AM[2:0] bits of the CHCFG\_m register can be used to make the settings as follows.

Table 19.6-17 DMAACK Output Timing Setting

| Mode      | AM[2]<br>(CHCFG_m) | AM[1:0]<br>(CHCFG_m) | REQD<br>(CHCFG_m)                                                        | Usage                                                                                                                                                                                        |
|-----------|--------------------|----------------------|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pulse     | 0b                 | 00b                  | 0b (Active at the time of reading)<br>1b (Active at the time of writing) | DMAACK is output with a pulse. Use this mode when the unit to which DMAACK is connected can receive DMAACK with a pulse.                                                                     |
| Level     | 0b                 | 01b                  | 0b (Active at the time of reading)<br>1b (Active at the time of writing) | DMAACK is output with a level. DMAACK continues to be asserted until DMAREQ is de-asserted. Use this mode when this output is asynchronous with the destination to which DMAACK is connected |
| Bus cycle | 0b                 | 10b<br>11b           | 0b (Active at the time of reading)<br>1b (Active at the time of writing) | DMAACK is output during the bus cycle period. Use this mode when DMAACK is to be asserted until the completion of a bus cycle.                                                               |
| Masking   | 1b                 | —                    | —                                                                        | DMAACK is fixed at the low level. Use this mode when DMAACK is not to be issued to the destination for connection.                                                                           |

## (2) Pulse Output

Setting the AM bits of the CHCFG\_m register to 000 selects pulse output.

Figure 19.6-16 DMAACK Output Timing (AM[2:0] = 000b, LVL = 0b)

When REQD = 0b, DMAACK is asserted when a bus cycle for reading starts.

When REQD = 1b, DMAACK is asserted when a bus cycle for writing starts.

(3) Level Output

Setting the AM bits of the CHCFG\_m register to 001 selects level output. DMAACK continues to be asserted until DMAREQ is de-asserted.

Figure 19.6-17 DMAACK Output Timing (AM[2:0] = 001b, LVL = 1b, REQD = 0b)

Figure 19.6-18 DMAACK Output Timing (AM[2:0] = 001b, LVL = 1b, REQD = 1b)

#### (4) Bus Cycle Output

Setting the AM bits of the CHCTRL\_m register to 010 selects bus cycle output. DMAACK is at the active level during the bus cycle period.

DMAREQ is masked within this unit while DMAACK is at the active level. Accordingly, even if DMAREQ is set for level detection, the output side does not need to de-assert it once.

Figure 19.6-19 Bus Cycle Output Timing (AM[2:1] = 01b, LVL = 1b, REQD = 0b)

- When the signal is at the active level at the time of reading (REQD = 0b), DMAACK is at the active level during the period from the start of the read cycle to one cycle after the end of the read cycle.
  - Start of the read cycle: MARVALID = 1b
  - End of the read cycle: MRVALID & MRLAST & MRREADY = 1b

Figure 19.6-20 Bus Cycle Output Timing (AM[2:1] = 01b, LVL = 0b, REQD = 1b)

- When the signal is at the active level at the time of writing (REQD = 1b), DMAACK is at the active level during the period from the start of the write cycle to one cycle after the end of the write cycle.
  - Start of the write cycle: MAWVALID = 1b
  - End of the write cycle: MBVALID & MBREADY = 1b

### 19.6.2.5 DMA Transfer Completed Interrupt

DMAEND[7:0] are interrupt request signals that indicate the completion of a DMA transaction.

Each bit of DMAEND[7:0] corresponds to a respective channel.

If a transfer for the total number of transfer bytes loaded to CRTB (Current Transaction Byte) is completed with an OKAY response, END of the CHSTAT\_m register is set to 1b. If DEM of the CHCFG\_m register = 0b at this time, the high level is output from the DMAEND[n] pin (n = 7 to 0) (when write-back proceeds in link mode, the high level is output after the completion of write-back).

In link mode, if LV = 0b in the header of the descriptor that has been read, DER of the CHSTAT\_m register is set to 1b. If DIM of the header = 0 at this time, the high level is output from the DMAEND[n] pin.

Use this signal for detection of a transfer completed interrupt by the interrupt controller.

Table 19.6-18 DMAEND Assertion Conditions

| Source                             | Condition                                                                                                                                                                                                   | DMAEND[n] Mask Signal           |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|
| Completion of the DMAC transaction | A transfer for the total number of transfer bytes loaded to CRTB (current transaction byte) being completed with an OKAY response (after the completion of write-back if write-back proceeds in link mode). | DEM bit of the CHCFG_m register |
| Descriptor invalid                 | In link mode, LV = 0b in the header of the descriptor that has been read while DIM of the header = 0b.                                                                                                      | DIM bit of the header           |

### 19.6.2.6 DMA Error Interrupt (DMAERR)

If an error response is received in DMA transfer and descriptor access, this unit judges this to be an error and stops transfer. If an error response is received, the EN bit of the CHSTAT\_m register for channel n during transfer is cleared to 0 and the ER bit is set to 1b (n = 0 to 7). Also, the high level is output from the DMAERR pin (on the other hand, DMAERR is not output if an error occurs in access to a slave of this unit).

The DMAERR signal cannot be masked.

The series of transfers which causes the error does not guarantee that data. Be sure to start transfer over again from the beginning by following the procedure below.

1. Set the SWRST bit of the CHCTRL\_m register to 1b.
2. Re-set each register.

Figure 19.6-21 Timing of Stopping Transfer by an Error Response (ERROR)

19.6.2.7 Interval Counting

The interval between the execution of DMA transfers can be adjusted by the setting of the ITVL bit of the channel interval register (CHITVL\_m). This functionality is intended to make sure that the DMA controller does not occupy the bus.

When one round of reading or writing is completed, counting down starts from the value set in CHITVL\_m. A next internal request is not executed until the value counted reaches to 0.

The figure below shows an example of operations.

Figure 19.6-22 Interval Counting

19.6.2.8 Differences in Operation with the Transfer Size

(1) When the Transfer Size of the Source is Small

When reading of data corresponding to the destination transfer size is completed, writing to the destination proceeds.

The figure below is a timing chart when the transfer size of the source is 8 bits and that of the destination is 32 bits (in the case of rising-edge detection).

Figure 19.6-23 When the Transfer Size of the Source is Small (LVL of CHCFG\_m = 0b, HIEN = 1b, REQD = 0b, SDS < DDS)

(2) When the Transfer Size of the Destination is Small

Since the transfer size of the source is larger than that of the destination, after reading from the source once, writing to the destination proceeds several times. The figure below is a timing chart when the transfer size of the source is 64 bits and that of the destination is 16 bits (in the case of rising-edge detection and (REQD of the CHCFG\_m register is set to 1).

Figure 19.6-24 When the Transfer Size of the Destination is Small (LVL of CHCFG\_m = 0b, HIEN = 1b, REQD = 1b, SDS > DDS)

(3) When the Transfer Sizes of the Source and Destination are the Same

Reading from the source and writing to the source proceed every time a DMA transfer request is detected.

The figure below is a timing chart when the transfer sizes of the source and destination are 8 bits (in the case of rising-edge detection and when REQD of the CHCFG\_m register is set to 1b).

Figure 19.6-25 When the Transfer Sizes of the Source and Destination are the Same (LVL of CHCFG\_m = 0b, HIEN = 1b, REQD = 0b, SDS = DDS)

19.6.2.9 Transfer State

The channel status register indicates the DMA transfer state of the channel.

(1) Transfer State

The transfer state is indicated by TACT as shown below.

Figure 19.6-26 DMAC State Example 1 (Hardware Request)

Figure 19.6-27 DMAC State Example 2 (Software Request)

(2) Suspension

The SETSUS bit of CHCTRL\_m can be used to suspend DMA transfer. At that time, if the bus cycle is already in progress, the DMAC is suspended after waiting for the completion of the cycle. It can be resumed from the suspended state by writing 1b to the CLRSUS bit.

Figure 19.6-28 DMAC Suspended State (Block Transfer by Software Request)

In the above case, the DMAC is suspended at the time read transfer is completed. If the DMAC has already executed transfer, it is suspended at the time that transfer is completed. To confirm that the transfer is suspended, set SETSUS and then check that the SUS bit for the corresponding channel is 1b by reading the CHSTAT or DST\_SUS register.

### (3) Aborting Transfer

Writing 1 to CLREN during the DMA transaction aborts the DMA transaction by the corresponding channel. As processing after the transaction has been aborted, select either of the following modes by using the SBE bit in the CHCFG\_m register: the mode where the data remaining in the buffer are flushed at the time the transaction is aborted (SBE = 1b) and the mode where the data are not flushed (SBE = 0b). By default, SBE = 0b.

When the transfer in progress is aborted by setting CLREN to 1b while this flushing mode is enabled, if data remain in the buffer of the DMAC, that data are flushed before the transaction is completed.

#### (a) Aborting Transfer (No Buffer Flushing: SBE = 0b)

When CLREN is set during DMA transfer, the DMA transfer is aborted and then stopped. The timing of stopping the transfer depends on the value set in REQD. After the transfer has been stopped, be sure to clear the internal state of the DMAC before making the settings for next transfer.

Figure 19.6-29 Aborting DMA Transfer

- Complete stopping of the channel can be confirmed at the time the TACT bit is cleared.
- If the DMA transfer in progress is aborted, the DMAEND pin is not asserted.
- If REQD = 0b, the transfer is stopped at the time next reading is completed. Note that if the buffer contains data that can be written, the transfer is stopped after the data are written.
- If REQD = 1b, the transfer is stopped at the time next writing is completed.

**(b) Aborting Transfer (with Buffer Flushing: SBE = 1b)**

Setting CLREN during DMA transfer aborts the DMA transfer. If REQD = 0b, data that have already been read are flushed (written) and then the DMA transfer is stopped. After the transfer has been stopped, set SWRST and clear the internal state of the DMAC before making the settings for next transfer.

If flushing mode is used when a hardware request is in use while REQD = 1b, data that have been read in advance may be written, so only use this mode while REQD = 0b.

Figure 19.6-30 Aborting DMA Transfer (Buffer Flushing Mode)

- Complete stopping of the channel can be confirmed at the time the TACT bit is cleared.
- If the transfer is aborted during the fifth read transfer in flushing mode (SBE = 1b), the DMAC is stopped after writing the data that have been read.

**(c) Checking stopping of the channel**

Even if the EN bit is cleared to 0, the DMAC cannot be stopped immediately if transfer has already been executed on the bus. Accordingly, to confirm that the DMAC has been stopped completely, check that both the EN and TACT bits are 0b.

**(d) Procedure for aborting transfer**

The following describes the procedure for stopping transfer.

1. Set SETSUS of CHCTRL\_m.
2. Poll the SUS bit of CHSTAT\_m until it becomes 1 (if EN is already 0b at this time, proceed to step 6 because the DMAC has been stopped).
3. Set CLREN of CHCTRL\_m.
4. If SBE = 0b, the DMAC is stopped according to the value of REQD, and if SBE = 1b, the data are flushed. If the setting of SBE = 1b, set REQD = 0b beforehand.
5. Read CHSTAT\_m to check that the TACT bit is 0b. TACT = 0b means that the DMAC has been stopped completely. If TACT = 1b, poll this bit until it becomes 0b.
6. To proceed with a next DMA transfer after aborting the transfer, be sure to set the SWRST (software reset) bit of CHCTRLn before the next transfer starts.

Figure 19.6-31 Flow of Aborting Transfer

### 19.6.3 AXI Address Conversion

Two bank switching address bits input by SYS are appended to the higher-order bits of the AXI master addresses to extend them to 34-bit master addresses, which makes a 16-GB address space accessible.

Since three bank switching addresses for the source, destination, and descriptor are input per DMAC number and channel number, the source, destination, and descriptor areas can be set in separate 4-GB address spaces.

Bank switching addresses are set by using the registers of the SYS unit.

The figure below shows an example of access to the 16-GB address space.

Figure 19.6-32 Example of Access to the 16-GB Address Space

#### (1) Descriptor read

- Access to a desired 4-GB address space is possible by setting the bank switching address (for the descriptor) for the corresponding DMAC number and channel.
- In the example of the above figure, the setting is 3.
- Setting is only required when link mode is in use.

#### (2) DMA transfer (source data read)

- Access to a desired 4-GB address space is possible by setting the bank switching address (for the source) for the corresponding DMAC number and channel.
- In the example of the above figure, the setting is 1.

(3) DMA transfer (destination data write)

- Access to a desired 4-GB address space is possible by setting the bank switching address (for the destination) for the corresponding DMAC number and channel.
- In the example of the above figure, the setting is 0.

(4) Descriptor write-back

- The same area as that in step 1.

### 19.6.3.1 Prohibited Items

This function has the following prohibited items.

- Changing a bank switching address value for a DMAC number and channel that is currently operating is prohibited.
- Usage that spans the 4-GB boundaries is prohibited.

## 19.7 Operating Procedure

For the individual setting procedures, see the following. The following gives supplementary information.

### 19.7.1 Example DMAC Settings

This section describes example settings when DMA transfer is to proceed with the use of the DMAC unit.

The conditions for transfer with the individual example settings are listed below.

Table 19.7-1 List of the Conditions for Transfer with Example DMA Transfer Settings

|                   | DMA Mode                           | Transfer Mode | Transfer Request |
|-------------------|------------------------------------|---------------|------------------|
| Example setting 1 | Register                           | Single        | Hardware         |
| Example setting 2 | Register                           | Block         | Software         |
| Example setting 3 | Register<br>(continuous execution) | Block         | Software         |
| Example setting 4 | Link                               | Block         | Software         |

For details of the settings, see the individual example settings.

### 19.7.1.1 Example Setting 1 (Hardware Request in Register Mode)

The table below lists the settings when DMA transfer is to proceed with example setting 1.

Table 19.7-2 Example Setting 1 for DMA Transfer

| Item                             | Description                                           |                      |
|----------------------------------|-------------------------------------------------------|----------------------|
| Channel to be used               | 3                                                     |                      |
| DMA mode                         | Register                                              |                      |
| Transfer mode                    | Single transfer                                       |                      |
| Register set to be used          | Next0                                                 |                      |
| Transfer source/destination      | Transfer source                                       | Transfer destination |
|                                  | Start address                                         | 1111_0000h           |
|                                  | Address direction                                     | Incremental          |
|                                  | Transfer size                                         | 32 bits              |
| Number of bytes for DMA transfer | 64 bytes                                              |                      |
| DMAREQ/ACK/TCO                   | Select DMAREQ[3] and DMAACK[3].                       |                      |
| DMA transfer request             | Rising-edge detection by hardware (the DMAREQ[3] pin) |                      |
| DMAACK signal                    | Pulse output at the time of reading                   |                      |
| DMAEND masking                   | No                                                    |                      |
| AXI setting (PROT, CACHE)        | Initial value                                         |                      |

#### Example Setting 1

N0SA = 1111\_0000h (Transfer source address)

N0DA = 2222\_0000h (Transfer destination address)

N0TB = 0000\_0040h (Number of transfer bytes)

CHCFG = 0002\_2023h (Configuration)

CHITVL = 0000\_0000h (Interval)

CHEXT = 0000\_0000h (AXI setting)

Figure 19.7-1 Example Setting 1

### 19.7.1.2 Example Setting 2 (Software Request in Register Mode)

The table below lists the settings when DMA transfer is to proceed with example setting 2.

Table 19.7-3 Example Setting 2 for DMA Transfer

| Item                             | Description                     |                      |             |
|----------------------------------|---------------------------------|----------------------|-------------|
| Channel to be used               | 2                               |                      |             |
| Priority control                 | Round-robin                     |                      |             |
| DMA mode                         | Register                        |                      |             |
| Transfer mode                    | Block transfer                  |                      |             |
| Register set to be used          | Next1                           |                      |             |
| Transfer source/destination      | Transfer source                 | Transfer destination |             |
|                                  | Start address                   | 0FFF_E000h           | 3333_0000h  |
|                                  | Address direction               | Incremental          | Incremental |
|                                  | Transfer size                   | 8 bits               | 256 bits    |
| Number of bytes for DMA transfer | 128 bytes                       |                      |             |
| DMAREQ/ACK/TCO                   | Select DMAREQ[7] and DMAACK[7]. |                      |             |
| DMA transfer request             | Software request                |                      |             |
| DMAACK signal                    | Masking                         |                      |             |
| DMAEND masking                   | No                              |                      |             |
| AXI setting (PROT, CACHE)        | Initial value                   |                      |             |

#### Example Setting 2

DCTRL = 0000\_0001h (DMAC setting)

N1SA = 0FFF\_E000h (Transfer source address)

N1DA = 3333\_0000h (Transfer destination address)

N1TB = 0000\_0080h (Number of transfer bytes)

CHCFG = 1045\_0407h (Configuration)

CHITVL = 0000\_0000h (Interval)

CHEXT = 0000\_0000h (AXI setting)

Figure 19.7-2 Example Setting 2

### 19.7.1.3 Example Setting 3 (Continuous Execution in Register Mode)

The table below lists the settings when DMA transfer is to proceed with example setting 3.

Table 19.7-4 Example Setting 3 for DMA Transfer

| Item                      |                                  | Description                           |                      |
|---------------------------|----------------------------------|---------------------------------------|----------------------|
| Channel to be used        |                                  | 1                                     |                      |
| Priority control          |                                  | Round-robin                           |                      |
| DMA mode                  |                                  | Register                              |                      |
| Transfer mode             |                                  | Block transfer                        |                      |
| Register set to be used   |                                  | Continuous from Next0 to Next1        |                      |
| Next0                     |                                  | Transfer source                       | Transfer destination |
|                           | Start address                    | 1111_0000h                            | 3333_0000h           |
|                           | Address direction                | Fixed                                 | Fixed                |
|                           | Transfer size                    | 32 bits                               | 512 bits             |
|                           | Number of bytes for DMA transfer | 512 bytes                             |                      |
| Next1                     |                                  | Transfer source                       | Transfer destination |
|                           | Start address                    | 2222_0000h                            | 4444_0000h           |
|                           | Address direction                | Fixed                                 | Fixed                |
|                           | Transfer size                    | 32 bits                               | 512 bits             |
|                           | Number of bytes for DMA transfer | 2048 bytes                            |                      |
| DMAREQ/ACK/TCO            |                                  | Select DMAREQ[7] and DMAACK[7].       |                      |
| DMA transfer request      |                                  | Software request                      |                      |
| DMAACK signal             |                                  | Not output                            |                      |
| DMAEND masking            |                                  | Masking DMAEND on completion of Next0 |                      |
| AXI setting (PROT, CACHE) |                                  | Initial value                         |                      |

#### Example Setting 3

DCTRL = 0000\_0001h (DMAC setting)

N0SA = 1111\_0000h (Transfer source address)

N0DA = 3333\_0000h (Transfer destination address)

N0TB = 0000\_0200h (Number of transfer bytes)

N1SA = 2222\_0000h (Transfer source address)

N1DA = 4444\_0000h (Transfer destination address)

N1TB = 0000\_0800h (Number of transfer bytes)

CHCFG = 6176\_2007h (Configuration)

CHITVL = 0000\_0000h (Interval)

CHEXT = 0000\_0000h (AXI setting)

Figure 19.7-3 Example Setting 3

#### 19.7.1.4 Example Setting 4 (Link Mode)

The table below lists the settings when DMA transfer is to proceed with example setting 4.

Table 19.7-5 Example Setting 4 for DMA Transfer

| Item                     | Description    |
|--------------------------|----------------|
| Channel to be used       | 0              |
| Priority control         | Round-robin    |
| DMA mode                 | Link           |
| Transfer mode            | Block transfer |
| Register set to be used  | —              |
| Descriptor start address | 0000_1000h     |

Table 19.7-6 Example Setting 4 for DMA Transfer (Descriptor 1)

| Item                          |                                  | Description                     |                      |
|-------------------------------|----------------------------------|---------------------------------|----------------------|
| Descriptor start address      |                                  | 0000_1000h                      |                      |
| Next descriptor start address |                                  | 0000_2000h                      |                      |
| Transfer mode                 |                                  | Block transfer                  |                      |
| Next0                         |                                  | Transfer source                 | Transfer destination |
|                               | Start address                    | 1111_0000h                      | 3333_0000h           |
|                               | Address direction                | Incremental                     | Incremental          |
|                               | Transfer size                    | 32 bits                         | 32 bits              |
|                               | Number of bytes for DMA transfer | 2048 bytes                      |                      |
| DMAREQ/ACK/TCO                |                                  | Select DMAREQ[0] and DMAACK[0]. |                      |
| DMA transfer request          |                                  | Software activation (STG)       |                      |
| DMAACK signal                 |                                  | Not output                      |                      |
| DMAEND masking                |                                  | Yes                             |                      |
| AXI setting (PROT, CACHE)     |                                  | Initial value                   |                      |
| Header                        |                                  |                                 |                      |
|                               | DMAEND when LV = 1b              | Issued (DIM = 0b)               |                      |
|                               | LV write-back                    | Yes (WBD = 0b)                  |                      |

Figure 19.7-4 Example Setting 4

### 19.7.1.5 Setting for Next Register Continuous Execution

The figure below is a flowchart when DMA transfer continues with the use of two Next register sets in register mode. While the DMA transaction of one Next register is in progress, the other Next register is set to continue with DMA transfer.

Figure 19.7-5 Schematic View of Next Register Continuous Execution

Figure 19.7-6 Example Setting 5

### Supplementary Information

Store the first register sets (0 (N0SA, N0DA, N0TB) , 1 (N1SA, N1DA, N1TB)) to be transferred in general-purpose registers of the CPU (this register value called \$CR for convenience).

Every time DMA transfer of one register set is completed (DMAEND is asserted), REN is automatically cleared to 0b. To continue transfer, REN of the CHCFG\_m register must be set every time DMAEND is asserted. The same register also has the setting bit of RSEL, so this value must also be set correctly. To do this, use \$CR.

In this mode, two Next registers are executed consecutively. However, if CLREN is not set by the time the DMA transaction is completed (next DMAEND is asserted ), continuous execution stops. In such cases, check how far the transfer has proceeded by reading the SR and EN bits of the CHSTATn register and REN of the CHCFG\_m register. To resume the transfer, follow the procedure in the above flowchart.

## 19.8 Points for Caution

### 19.8.1 Problem of DMAACK Overtaking DMA Transfer

When contention between access by this unit and access by another master arises or there is a bus bridge between this unit and the device that asserted the DMAREQ signal, DMA transfer may be delayed relative to assertion of the DMAACK signal.

In cases where the DMAACK signal is asserted but the corresponding bus access has not yet arrived, if the device that asserted the DMAREQ signal for the unfinished transfer asserts this signal again, DMA transfers may overlap.

Make sure that a device that asserts the DMAREQ signal does not assert this signal twice for a single DMA transfer activation source.

The following describes an example where DMA transfer is delayed relative to the assertion of the DMAACK signal.

#### 19.8.1.1 Example Circuit 1 where DMA transfer is Delayed Relative to the DMAACK Signal

This unit starts to assert the DMAACK signal simultaneously with the start of transfer (MARVALID (or MAWVALID) is at the high level) even when the MARREADY (or MAWREADY) signal is at the low level. This start timing does not depend on the level of the MARREADY (or MAWREADY) signal.

For example, in the case of the circuit shown below, if this unit attempts to access slave A while master A has access to slave A, a low level is returned as the MARREADY signal by the AXI interconnect and transfer by this unit may be held pending, but the DMAACK signal will still be asserted.

As a result, a time lag is generated between assertion of the DMAACK signal and the actual time at which transfer on the bus becomes possible.

Figure 19.8-1 Example: Circuit where a Wait Causes a Delay from Activation of the DMAACK Signal to Actual Access

### 19.8.1.2 Example Circuit 2 where DMA transfer is Delayed Relative to the DMAACK Signal

If a device that receives DMAACK is connected to a different bus from that of this unit, a difference may be generated between access to that device by this unit and access until DMAACK is reached.

Figure 19.8-2 Example: Circuit where a Delay from Activation of the DMAACK Signal to Actual Access is Caused via a Bus Bridge

### 19.8.1.3 Example Circuit 3 where DMA transfer is Delayed Relative to the DMAACK Signal

Due to the configuration of the internal circuit, the MARVALID (or MAWVALID) signal is asserted with a delay of one or more cycles relative to the DMAACK signal.

## 19.8.2 Problem of the Interrupt Signal Overtaking DMA Transfer

### 19.8.2.1 Overview

This unit asserts the DMAINT interrupt signal on completion of transfer and this serves as a trigger for the CPU to start processing the data.

However, in cases such as where the device for writing is on another bus, the final data to be written may not yet have reached the device for writing at the time the DMAINT interrupt signal is asserted.

If the CPU accesses a device that has detected the DMAINT interrupt signal before the final data of the DMA transaction have been written to the device, it may be using some old data from before the writing.

Figure 19.8-3 Example when Access by the CPU Overtakes Writing of the Final Data by the DMAC

### 19.8.2.2 Workarounds

The following describes workarounds for the above problems.

#### Workaround 1: Setting AWPROT as non-bufferable

Set the MAWPROT signal as non-bufferable for DMA transactions. By doing this, the above problems can be avoided because the DMAINT interrupt signal will only be asserted after the completion of writing to the device for access.

Setting all transfers to non-bufferable may reduce the efficiency of transfer. In such cases, divide up the register sets or descriptors by setting most of the transactions to bufferable for transfer, and then set only the last transfer to non-bufferable.

*Exception)*

The effect is not obtained if the device in the access path does not refer to AWPROT.

#### Workaround 2: Dummy access to the last written address by this unit

The completion of writing data is guaranteed by asserting the DMAINT interrupt signal after dummy reading the last written address area from this unit and then dummy writing it to the area that does not affect operation.

In register mode, set the main DMA transfer in one register set and set dummy access in the other register set. Since masking of the interrupt is automatically removed on completion of the DMA transaction of one register set, the interrupt can be asserted after dummy access.

In link mode, prepare a descriptor for dummy access and configure a descriptor chain such that this descriptor is accessed after the main DMA transfer. Since masking of the interrupt can be set in the descriptor, so mask the interrupt in the main DMA transaction and de-assert the interrupt in dummy access beforehand.

*Exception)*

This workaround cannot be used if dummy reading of the device affects its operation.

It also cannot be used if transfer is through a device for which the order of reading and writing may be reversed. The order of reading and writing may be reversed in the AXI bus. If this is the case, set ARPROT and AWPROT to non-bufferable for transfer.

#### Workaround 3: Polling the descriptor

Use link mode to provide descriptors in slave A and enable descriptor write-back to start DMA transfer.

This unit asserts the DMAINT interrupt signal after writing back the descriptor following the last DMAC write transfer. Make sure that the CPU refers to the last DMA write data after polling the descriptor in slave A to check that it has been written back.

*Exception)*

This workaround cannot be used if descriptors cannot be located in the device. In such cases, handle the problem by locating descriptors in another device on the same bus as the device, or a similar measure.

## Section 20 Interrupt Controller (GIC)

This section describes the functions of the interrupt controller (GIC).

### 20.1 Functional Overview

The GIC incorporates the Arm® CoreLink™ GIC-400 generic interrupt controller from ARM. For details on the GIC-400, see *the ARM CoreLink GIC-400 Generic Interrupt Controller Technical Reference Manual*.

**Table 20.1-1** lists a summary of the functions.

Table 20.1-1 Functional Overview

| Item                        | Functions                                                                                                                                                                                                         |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Interrupt controller        | GIC-400 generic interrupt controller r0p1<br>Compliant with ARM generic interrupt controller architecture version 2.0                                                                                             |
| Supported interrupt factors | <ul style="list-style-type: none"><li>• SGI (software generated interrupt): 16 factors</li><li>• PPI (private peripheral interrupt): 6 factors</li><li>• SPI (shared peripheral interrupt): 480 factors</li></ul> |

#### 20.1.1 GIC Configuration

**Table 20.1-2** lists the GIC configuration.

Table 20.1-2 GIC Configuration

| Item                           | Setting |
|--------------------------------|---------|
| Number of supported processors | 2       |
| Number of supported SPIs       | 480     |
| ID width of AXI read channel   | 10      |
| ID width of AXI write channel  | 10      |

## 20.2 Address Space

The register of the GIC is arranged in 4-KB address boundaries for individual functions. In the GIC of this LSI, it is reallocated to 64-KB address boundaries in order to support the virtualization feature of ARM-v8 architecture. **Figure 20.5-1** shows the relationship between the GIC address and the system address.

### CAUTION

**GIC Address:** Addresses defined in the ARM GIC-400 specifications

**System Address:** Address of the GIC unit in this LSI

Figure 20.5-1 Relationship between the GIC Address and the System Address

Table 20.5-1 Address Space for GIC Functions

| System Address                     | GIC Address    | GIC Functions                                                                    | Abbreviation |

## 20.3 Register Descriptions

The GIC is the Arm® CoreLink™ GIC-400 generic interrupt controller.

The revision number of the IP module is r0p1.

For the details of these registers, refer to the ARM manual shown below.

- *ARM CoreLink GIC-400 Generic Interrupt Controller Technical Reference Manual*

## 20.4 Functional Description

For details on the functions of the GIC, see *the ARM CoreLink GIC-400 Generic Interrupt Controller Technical Reference Manual*.

## Section 21 CMOS Image Sensor Interface (CIF)

This section describes the functions of the CMOS image sensor interface (CIF).

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 21.1 Functional Overview

The CIF has the MIPI CSI-2 D-PHY and link which support the MIPI CSI-2 Ver1.2 interface.

The main functions of CIF are listed in **Table 21.1-1**.

Table 21.1-1 Function Overview

| Classification                      | Description                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CMOS image sensor interface (D-PHY) | <ul style="list-style-type: none"> <li>• Supports MIPI D-PHY ver1.2</li> <li>• Transfer rate:<br/>MIPI D-PHY: Max. 2.5 Gbps/lane</li> <li>• Maximum input clock frequency: Up to 1.25 GHz</li> <li>• Maximum number of lanes: Data: 4 lanes × 2 + Clock: 2 lanes</li> <li>• 8-bit/lane parallel output: 8 bits</li> <li>• 2 sensor input*<sup>1</sup></li> </ul>              |
| CMOS image sensor interface (Link)  | <ul style="list-style-type: none"> <li>• Conforms to the MIPI Alliance Specification for Camera Serial Interface 2 (CSI-2) v1.2<br/>(Note: Ultra-low power mode is not supported.)</li> <li>• RAW8/10/12, YUV422*<sup>2</sup>, User defined byte-based data supported</li> <li>• Short/long packet supported</li> <li>• WDR supported (DOL DINFO, virtual channel)</li> </ul> |

Note 1. Using 2 sensor input requires software provided by a partner company. For details, contact a Renesas Electronics sales representative.

Note 2. The input of data in this format limits the available functions of the LSI chip. For details, contact a Renesas Electronics sales representative.

#### 21.1.1 Conforming Standards

- Conforms to the MIPI Alliance Specification for Camera Serial Interface 2 (CSI-2) version 1.2
- MIPI Alliance Specification for D-PHY Version 1.2

## Section 22 Image Sensor Timing Generator (STG)

This section describes the functions of the image sensor timing generator (STG).

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 22.1 Functional Overview

The STG unit generates the timing for CMOS image sensors.

- Timing generation for image sensors

The image sensor timing generator (STG) is connected to the CMOS image sensor or sensors to generate the timing for synchronization. The STG internally generates a synchronization signal and supplies it to the image sensor in master mode.

- VD/HD generation/output for image sensors

One or two image sensors can be connected to the STG. When two image sensors are in use, there are two choices in terms of synchronization. With synchronous driving, both sensors operate with the same timing; with asynchronous driving, the timing for each sensor is completely separate from that for the other.

- Serial interface dedicated for image sensors

For serial communications for controlling the image sensor (or sensors), 4-wire clock-synchronous serial communications and IIC communications are available. Both types of communications support the automatic sending of values for setting by a dedicated DMAC and transfer in both directions under CPU control.

- Generation of shutter triggers

The STG also has functionality for issuing an interrupt with a desired timing in terms of image-sensor driving and for the output of timing pulses to control mechanical shutters, strobes, and other devices of the imaging system.

## Section 23 Audio Interface (AUI)

This section describes the functions of the audio interface (AUI).

These functions are supported with the optional APIs.

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 23.1 Functional Overview

The AUI supports DMA transfer and can send and receive data to and from audio devices that support the I2S interface. The audio device is used as the master and the AUI is used as the slave.

- I2S interface:
  - Slave mode
  - MSB first
  - AUBICK frequency 64 fs (fs: sampling rate)
- Audio format: Linear PCM 8/16 bits, monaural/stereo

## Section 24 AI Accelerator (DRP-AI)

This section describes the functions of the AI accelerator (DRP-AI).

### 24.1 Functional Overview

The AI accelerator contains a DRP and an AI-MAC, which are called DRP-AI. It uses the information on the LPDDR4 memory to perform AI inference and store the results.

The DRP-AI is an AI accelerator that can execute AI inference independently of the CPU. The DRP-AI works by the DRP-AI driver reading the descriptor for converting trained AI models by the DRP-AI translator.

- DRP-AI translator: Conversion tool to be provided separately
- DRP-AI driver: Linux device driver to be provided separately

## 24.2 Block Diagram

The AI accelerator contains a DRP and an AI-MAC.

### ■ DRP (programmable hardware)

[Configuration]

- DRP: Reconfigurable core
- DMAC: Improves the efficiency of data transfer

### ■ AI-MAC (hardware for high-speed processing of 16-bit floating-point (FP16) matrix operations)

[Configuration]

- MAC (multiply-accumulate calculator): Matrix multiply-accumulate operations
  - Local memory (SRAM for this unit): Holds matrix data, and the weight and bias values of the learning results.
- DMAC: Transfers matrix data, and weight and bias values from LPDDR4 to the local memory.  
Transfers the result of the multiply-and-accumulate operation output by MAC to LPDDR4.

Figure 24.2-1 Block Diagram of AI Accelerator

### 24.3 Inference Operation Example on DRP-AI

**Figure 24.3-1** shows the inference operation example. The DRP-AI can perform AI inference with the DRP and AI-MAC. This operation is performed automatically by reading the descriptor thorough the DRP-AI driver after kicking the API. When AI inference is completed, the DRP-AI sends the interrupt flag to the CPU.

Figure 24.3-1 Inference Operation Example on DRP-AI

## Section 25 Multi-Target Detection (MTD)

This section describes the functions of the multi-target detection (MTD).

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 25.1 Functional Overview

The MTD detects faces and human bodies from input images and provides information on the number of detected faces or bodies, and their sizes and locations.

- Input image format: 8-bit luminance (Y)
- Input image size:  $320 \times 240$  /  $640 \times 480$  /  $720 \times 480$  /  $960 \times 540$
- Targets for detection: Faces, human bodies
- Summary for output: Number of detected items, sizes, center coordinates

### 25.2 Functional Description

#### 25.2.1 Face Detection

The specification of the face detection function is as follows:

- The number of simultaneous detections: 35 (max.)
- Detection angle:  $\pm 45$  degrees relative to the reference direction for detection.
- Detection direction: Up, down, left, and right are supported.
- Incidental information on detection: Position, size, evaluation value (0 to 9), detection angle (0 to 359 degrees), and direction (front / right oblique / right side / left oblique / left side)

#### 25.2.2 Human Body Detection

The specification of the human body detection function is as follows:

- The number of simultaneous detections: 35 (max.)
- Detection angle:  $\pm 10$  degrees relative to the reference direction for detection.
- Detection direction: Up, down, left, and right are supported.
- Incidental information on detection: Position, size, evaluation value (0 to 9), detection angle (0, 90, 180, and 270 degrees)

## Section 26 General Processing Accelerator (GPA)

This section describes the functions of the general processing accelerator (GPA).

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 26.1 Functional Overview

- General-purpose image processing (color space conversion, general-purpose filters, data string operations, etc.)
- Various assistance functions (WDR)

## Section 27 Camera ISP (ISP)

This section describes the functions of the camera ISP (ISP).

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 27.1 Functional Overview

The ISP unit handles image processing of raw data captured from an image sensor.

- The camera ISP unit consists of the following three processing blocks.
  - Image sensor image capturing block
  - Development processing block (Bayer to YUV processing)
  - Post processing block (deformation processing)
- Input: Raw data RGBG Bayer 10/12 bits  
\*RGB-W and RGB-IR handling are also available options.
- Output: YUV422 8 bits
- Maximum resolution:  $12,800 \times 16,382$  pixels (when a single camera is connected) /  $6,400 \times 16,382$  pixels (when a dual camera is connected)
- Processing capacity:  $3840 \times 2160 \text{ p} \times 30 \text{ fps}$  /  $1920 \times 1080 \text{ p} \times 60 \text{ fps}$  /  $1920 \times 1080 \text{ p} \times 30 \text{ fps} \times 2$  /  $640 \times 480 \text{ p} \times 800 \text{ fps}$

## Section 28 H.265/H.264 Multi Codec (VCD)

This section describes the functions of the H.265/H.264 multi codec (VCD).

### 28.1 Functional Overview

The VCD is a video codec that supports H.264 and H.265. It has the features shown below.

- H.265/HEVC MP (main profile) supported  
H.265/HEVC main profile at level 5
- H.264/AVC constrained baseline/main/high profile supported  
High profile at level 4.2,  
Progressive high profile at level 4.2,  
Constrained high profile at level 4.2,  
Main profile at level 4.2,  
Constrained baseline profile at level 4.2
- H.265 encoding and decoding performance  
3840 × 2160 × 30 fps encoding, 3840 × 2160 × 30 fps decoding  
1920 × 1080 p × 60 fps encoding, 1920 × 1080 p × 60 fps decoding  
640 × 480 × 800 fps encoding
- H.264 encoding and decoding performance  
1920 × 1080 p × 60 fps encoding, 1920 × 1080 p × 60 fps decoding  
640 × 480 × 800 fps encoding
- Supports the rate control among HW frames when encoding
- Supports the tile structure during H.265 encoding (vertical division into two only)
- Supports VPS (H.265 only), SPS, PPS, and AUD coding and output functions by HW during encoding
- Equipped with lossless compression and reference image buffer to reduce memory bandwidth

## 28.2 Connection Configuration

**Figure 28.2-1** shows the connection configuration for the H.265/H.264 multi codec (VCD).

Figure 28.2-1 Configuration Diagram of VCD Connection

## 28.3 Operation Procedure

For VCD operations, APIs are defined. For details, see the ISP control software specification.

## Section 29 2D Graphics Engine (GRP)

This section describes the functions of the 2D graphics engine (GRP).

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 29.1 Functional Overview

This LSI is equipped with a 2D graphics core. The supported functions are as follows.

- Provides a wide variety of graphics primitives such as lines, triangles, squares, and circles.
- Supports anti-aliasing and high-precision sub-pixel rendering.
- Bezier line and bezier segment generation
- Flexible colorization using multiple paths
- Dedicated clearing unit to clear memory area with maximum bandwidth
- Texture size:  $4096 \times 4096$

## Section 30 JPEG Codec (JPG)

This section describes the functions of the JPEG codec (JPG).

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 30.1 Functional Overview

The JPG is a unit for compression/decompression of still images according to the baseline process (BASELINE). As a compression/decompression process, it uses the discrete cosine transform (DCT), quantization, and Huffman code methods. The JPG is capable of processing up to 16 samples/clock.

#### (1) JPEG Function

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**(2) Data Input/Output Function**

The data input/output is performed by DMA transfer.

DMA function:

- DMA read function for image data arranged in raster on the memory
- DMA write function for image data to be arranged in raster on the memory
- DMA function for stream data to the memory

## Section 31 LPDDR4 Interface (LPDDR4)

This section describes the functions of the LPDDR4 interface (LPDDR4).

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 31.1 Overview

The LPDDR4 is a JEDEC 209-4A-compliant interface consisting of an LPDDR4 memory controller (MMC) and an LPDDR4 PHY interface (DDI) with the following functions.

- Supported data rate: 3200 Mbps
- Data bus width: 32 bits
- Supported memory capacities: 2 GB, 4 GB\*<sup>1</sup>
- Supports 1- and 2-rank memory\*<sup>1</sup>
- Operating modes:
  - Burst length: 16 (fixed)
  - Burst type: Sequential (fixed)
- ZQ calibration operation
- The following features for use with LPDDR4 are not supported:
  - MPC (multi-purpose command) is not supported except ZQ calibration
  - Modified refresh (for derating)
  - BL32 functionality
  - 12-Gb and 16-Gb (per channel) densities with byte mode

**Note 1.** This LSI supports the following LPDDR4 SDRAM devices.

1-rank memory: 2 GB

2-rank memory: 4 GB

## Section 32 SD Host Interface (SDI)

This section describes the functions of the SD Host interface (SDI).

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 32.1 Functional Overview

The SDI blocks mainly consist of the SD interface, which is the main control block, and the sampling clock controller (SCC), which is the sampling clock control block. This LSI chip is equipped with two SDIs; SDI0 and SDI1, and they are compatible with SD-UHS-I SDR104.

SDI1 includes a fail-safe function.

### 32.2 Block Diagram

For more information, contact a Renesas Electronics sales representative.

## 32.3 Pin Functions

**Table 32.3-1** lists the external pins of the SDI..

Table 32.3-1 List of External Pins

| Pin name | I/O    | Function                       |
|----------|--------|--------------------------------|
| SDnCLK   | Output | Clock output (SDCLK)           |
| SDnCMD   | IO     | Command output, response input |
| SDnDAT0  | IO     | Data [bit 0]                   |
| SDnDAT1  | IO     | Data [bit 1], SDIO interrupt   |
| SDnDAT2  | IO     | Data [bit 2], Read wait        |
| SDnDAT3  | IO     | Data [bit 3], Card detection   |
| SDnWP    | Input  | Write protection               |
| SDnCD    | Input  | Card detection                 |

**Note:** SDn (= SD0, SD1F) is the prefix of the SDIO/SDI1 interface

## 32.4 Address Map

**Table 32.4-1** lists the register address map.

Table 32.4-1 Register Address Map

| Module       | Address       |
|--------------|---------------|
| SD interface | 0000h - 09FFh |
| SCC          | 1000h - 1FFFh |

## 32.5 SD Interface

### 32.5.1 Overview

- 2 units are included: SDI0, SDI1.
- All support SD memory/IO card interfaces (1-/4-bit SD bus).
- SD, SDHC, and SDXC SD memory card access are supported.
- Default, high-speed, UHS-I/SDR12, SDR25, SDR50, and SDR104 transfer modes are supported.
  - \* DDR50 is not supported.
  - \* SDR104 tuning is only supported for transfer at 200 MHz.
- SD clock (SDCLK) frequency = IMCLK\*<sup>1</sup> frequency/2<sup>n</sup> (n = 0 to 9).
- Error checking function: CRC7 (for command/responses), CRC16 (for data)
- Interrupt requests: 2
- Card detection
- Write protection

**Note 1.** IMCLK: Main clock from CPG

## Section 33 eMMC Host Interface (eMMC)

This section describes the functions of the eMMC host interface (eMMC).

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 33.1 Functional Overview

The eMMC block mainly consists of the eMMC interface, which is the main control block, and the sampling clock controller (SCC), which is the sampling clock control block for the HS200 eMMC interface. The eMMC block is compatible with SD-UHS-I SDR104 and HS200 eMMC.

### 33.2 Block Diagram

For more information, contact a Renesas Electronics sales representative.

### 33.3 Pin Functions

**Table 33.3-1** lists the external pins of the eMMC.

Table 33.3-1 List of External Pins

| Pin name | I/O    | Function                       |
|----------|--------|--------------------------------|
| MMCLK    | Output | eMMC clock output (SDCLK)      |
| MMCMD    | IO     | Command output, response input |
| MMDAT0   | IO     | Data [bit 0]                   |
| MMDAT1   | IO     | Data [bit 1]                   |
| MMDAT2   | IO     | Data [bit 2]                   |
| MMDAT3   | IO     | Data [bit 3]                   |
| MMDAT4   | IO     | Data [bit 4]                   |
| MMDAT5   | IO     | Data [bit 5]                   |
| MMDAT6   | IO     | Data [bit 6]                   |
| MMDAT7   | IO     | Data [bit 7]                   |

### 33.4 Address Map

**Table 33.4-1** lists the register address map.

Table 33.4-1 Register Address Map

| Module         | Address       |
|----------------|---------------|
| eMMC interface | 0000h - 09FFh |
| SCC            | 1000h - 1FFFh |

## 33.5 eMMC Interface

This unit uses the same IP as that of the SDI and the use of SD cards may be described. Read the “SD card” as “eMMC”.

### 33.5.1 Overview

- eMMC interface (1-/4-/8-bit MMC bus)
- Only eMMC device access is supported.
- Backward-compatible, high-speed, and HS200 transfer modes are supported.
  - \* High-speed DDR and HS400 are not supported.
  - \* HS200 tuning is only supported for transfer at 200 MHz.
- High-priority interrupt (HPI) is supported.
- Boot operation and alternative boot operation are supported.
- eMMC clock (SDCLK) frequency = IMCLK\*<sup>1</sup> frequency/2<sup>n</sup> (n = 0 to 9).
- Error checking function: CRC7 (for command/responses), CRC16 (for data)

**Note 1.** IMCLK: Main clock from CPG

## Section 34 USB3.1 Gen1 Interface (USB)

This section describes the functions of the USB3.1 Gen1 interface (USB).

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 34.1 Functional Overview

This unit is composed of a USB3.1 Gen1 Dual Role Device controller (USB3DRD), a USB3.1 Gen1 Host controller (USB3HOST), a USB3.1 Gen1 Peripheral controller (USB3PERI), and a USB test module (USB3TEST). **Table 4.1-1** and **Table 34.1-2** list the functions in outline.

Table 34.1-1 Functions in Outline

| Item              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### 34.3 Pin Functions

**Table 34.3-1** lists the external pins of the USB.

Table 34.3-1 List of External Pins

| Pin name | I/O    | Function                                                                                     |
|----------|--------|----------------------------------------------------------------------------------------------|
| USDP     | IO     | USB2.0 USB D+ signal (positive)                                                              |
| USDM     | IO     | USB2.0 USB D- signal (negative)                                                              |
| USRESREF | Input  | Reference resistor connection pin<br>* To connect a pull-down resistor. Resistance: 200Ω ±1% |
| USVBUS   | Input  | USB 5-V signal detection pin<br>* Resistance partial pressure outside the chip* <sup>1</sup> |
| USRX0M   | Input  | USB3.1 super-speed differential reception pair (negative)                                    |
| USRX0P   | Input  | USB3.1 super-speed differential reception pair (positive)                                    |
| USTX0M   | Output | USB3.1 super-speed differential transmission pair (negative)                                 |
| USTX0P   | Output | USB3.1 super-speed differential transmission pair (positive)                                 |
| USOTGID  | Input  | ID detection (OTG ID input, 0: Host, 1: Peripheral)                                          |
| USPWEN   | Output | VBUS control signal (active high)                                                            |
| USOVC    | Input  | Overcurrent detection (active low)                                                           |

Note 1. For the details, see the section of Pin.

## 34.4 USB3.1 Gen1 Dual Role Device Controller (USB3DRD)

### 34.4.1 Introduction

The USB3.1 Gen1 Dual Role Device Controller (USB3DRD) complies with the Universal Serial Bus (USB) 3.1 Specification.

This unit operates in DRD mode.

#### 34.4.1.1 Features

The functions of the USB3DRD are outlined below.

##### (1) USB Functions

The USB3DRD is compliant with *the Universal Serial Bus 3.1 Specification Revision 1.0 and ECNs approved in June 27, 2017 and the Universal Serial Bus Specification Revision 2.0 and the Universal Serial Bus Specification Revision 2.0 and ECNs related to LPM functions* as of July 16, 2007 and October 11, 2011.

[Host Controller-portion]

- Supports 1 downstream port.
- Supports Super Speed (5 Gbps), High Speed (480 Mbps), Full Speed (12 Mbps), and Low Speed (1.5 Mbps).
- Supports all transfer-types: Control, Bulk, Interrupt, Isochronous, and these split-transactions.
- Supports Power Control and Over Current Detection.
- Implements the following USB2.0 ECNs USB 2.0 Link Power Management Addendum and LPM functions that are compliant with the xHCI specification.
  - USB 2.0 Link Power Management Addendum Engineering Change Notice to the USB 2.0 specification as of July 16, 2007
  - Errata for USB 2.0 ECN: Link Power Management (LPM) – 7/2007 as of October 11, 2011
- Compliant with *the eXtensible Host Controller Interface for the Universal Serial Bus Specification Revision 1.1*.

[Peripheral Controller-portion]

- Supports 1 upstream port.
- Supports Super Speed (5 Gbps), High Speed (480 Mbps), and Full Speed (12 Mbps). (Low Speed (1.5 Mbps) is not supported.)
- Supports Control, Bulk, and Interrupt transfers. (Isochronous is not supported.)
- Stream ID control supported (UASP can be supported)
- Supports Suspend/Resume function
  - USB3.1 Power Management by sending/receiving of link commands is supported (PHY clock stop is supported)
  - Remote Wakeup request can be transmitted
  - USB2.0 Link Power Management (LPM) is supported

## (2) Dual Role Device Function

The USB3DRD supports the following function that is compliant with *the On-The-Go and Embedded Host Supplement to the USB Revision 3.0 Specification Revision 1.1* as of May 10, 2012 (OTG and EH 3.0 Rev.1.1) and *On-The-Go and Embedded Host Supplement to the USB Revision 2.0 Specification Revision 2.0 version 1.1a* July 27, 2012 (OTG and EH 2.0 Ver.1.1a).

[On-The-Go]

- The USB3DRD supports the following function of On-The-Go (OTG).
  - Role swapping function by the ID pin of the Micro-AB receptacle

## (3) Battery Charging Functions

The USB3DRD supports the following functions that are compliant with *the Battery Charging Specification Revision 1.2*.

[Charging port device (Host Controller-portion)]

- The USB3DRD supports the following modes of chargeable portable devices.
  - Standard Downstream Port (SDP) Mode
  - Charging Downstream Port (CDP) Mode
  - Dedicated Charging Port (DCP) Mode

[Portable device (Peripheral Controller-portion)]

- The USB3DRD supports the following modes of portable devices.
  - Standard Downstream Port (SDP) Mode
  - Charging Downstream Port (CDP) Mode
  - Dedicated Charging Port (DCP) Mode
- The USB3DRD also supports the following function of portable devices.
  - Data Contact Detect (DCD)

## 34.4.2 Resets

### 34.4.2.1 Internal Reset Inputs

The USB3DRD has the following signals as the reset input.

Table 34.4-1 USB3DRD Reset Inputs Information

| Reset's Name | Description                                                                                                                                                                                                       |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| aresetn_h    | AXI bus reset signal to the AXI interface of the Host controller-portion.<br>This signal is also the HW Reset input for the whole Host controller-portion.<br>(This signal from CPG is USB_ARESETN_H)             |
| aresetn_p    | AXI bus reset signal to the AXI interface of the Peripheral controller-portion.<br>This signal is also the HW Reset input for the whole Peripheral controller-portion.<br>(This signal from CPG is USB_ARESETN_P) |
| drd_reset    | This signal is the HW Reset input for the whole USB3DRD's logic including both of the Host Controller-portion and the Peripheral Controller-portion.<br>(This signal from CPG is USB_DRD_RESET)                   |

### 34.4.3 Interrupts

#### 34.4.3.1 Interrupt Diagram

In the USB3DRD, the elements of interrupt are notified by the following layered structure.

The below red-colored interrupts are main interrupts.

Figure 34.4-1 USB3DRD Interrupts Structure

### 34.4.3.2 Interrupt Sources

The USB3DRD has the following three categories as the interrupt sources.

1. The related DRD specific's interrupt-elements
2. The related Host Controller-portion's interrupt-elements
3. The related Peripheral Controller-portion's interrupt-elements

#### (1) Related DRD Specific's Interrupt-Elements

The USB3DRD has the following interrupt sources as the related DRD specific's interrupt-elements.

Table 34.4-2 Information of Related DRD Specific's Interrupt-Elements (1/2)

| Interrupt Name | Type of Notification | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## (2) Related Host Controller-Portion's Interrupt-Elements

All interrupt-elements of the category "2" in **Section 34.4.3.2, Interrupt Sources** is logical ORed and output to "all\_int\_h".

Refer to the Host Controller-portion (USB3HOST)'s section for details.

## (3) Related Peripheral Controller-Portion's Interrupt-Elements

All interrupt-elements of the category "3" in **Section 34.4.3.2, Interrupt Sources** is logical ORed and output to "axi\_int\_all\_p".

Refer to the Peripheral Controller-portion (USB3PERI)'s section for details.

34.4.4 Registers Specification

For the register base address (<USB\_S1\_base>), see the section of Address Map.

34.4.4.1 Register Overview

When the USB3DRD core works in DRD mode, DRD registers are mapped in the AXI address space for the Peripheral role.

The AXI address map is as follows.

The 12-bit offset address space from 400h to 4FFh is mapped as the DRD Registers' address space.

Therefore, in this mode, DRD registers are accessed by using the AXI slave interface of the Peripheral Controller-portion.

(i.e. in this mode, DRD registers is not mapped in the AXI address space for the Host role.)

Figure 34.4-2 AXI Address Space for DRD Registers in DRD Mode

NOTE

The DRD registers are located in USB3DRD and are not located in EPC RAM of the Peripheral Controller-portion.

### 34.4.4.2 Registers List

#### (1) DRD Common Registers

Table 34.4-3 List of DRD Common Registers (1/2)

|                                                   | bit31           | bit30           | bit29         | bit28         | bit27         | bit26         | bit25              | bit24          |

| 440h<br>to 4FFh       | Reserved             | Each bit is read "0b" as the value.                        |          |

### 34.4.5 Register Descriptions

The function description of each register is given below.

The prefix (USB\_PERI\_) of the register names is omitted in the register descriptions and the field descriptions in this section.

#### 34.4.5.1 DRD Common Registers

##### (1) DRD Common Control Register (USB\_PERI\_DRD\_CON)

This register controls the common functions.

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + 0400h

**Initial Value:** 4100\_0000h

| Bit           | 31       | 30       | 29            | 28            | 27 | 26 | 25 | 24       | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16             |

(2) DRD Common Control 2 Register (USB\_PERI\_DRD\_CON2)

This register controls the common functions.

Access Size: 32 bits  
Address(es): <USB\_S1\_base> + 0404h  
Initial Value: 0000\_0000h

### 34.4.6 Description of Functions

The USB3DRD supports the following DRD-specific functions.

The prefix (USB\_PERI\_) of the register names is omitted in this and subsequent sections.

#### 34.4.6.1 DRD Mode

The USB3DRD supports the “DRD mode” in which role swapping function is enable by the ID pin “drd\_id”.

The default role is the peripheral role in this mode. ID pin “drd\_id” is needed to be set to the “Pull Up”’s situation. The role swapping event is occurred by the status change of the ID pin “drd\_id”.

The role’s selection is decided by USB3.1 Micro-AB receptacle. This receptacle can be connected by using the USB3.1 cable with USB3.1 Micro-A plug and USB3.1 Micro-B plug. This USB cable decides either "A-device" or "B-device" by connected USB plug. The “A-device” shall supply VBUS to USB bus and the “B-device” shall not supply VBUS to USB bus.

Therefore, the "A-device" is fixed as the "A-Host" and the "B-device" is fixed as the "B-Peripheral".

The ID pin’s status can be monitored by the register-bit “DRD\_STA.ID\_STA”, and this ID pin’s changed status can be monitored by the register-bit “DRD\_INT\_STA.ID\_CHG\_STA”. When the interrupt enable register-bit “DRD\_INT\_ENA.ID\_CHG\_ENA is set to “1b”, the event of this ID pin’s status change can be transmitted to the USB-SW’s system as the interrupted notification by the interrupt signal.

Both of the Host role’s SW driver “xHCI” driver and the Peripheral role’s SW driver are needed to be treated as the module.

Because, when the role-swapping is occurred, a driver for the active role shall be loaded and a driver for the inactive role shall be unloaded.

**(1) Power On**

Figure 34.4-3 Power-On Flowchart in DRD Mode

1. Set below external reset-inputs to the value to assert these reset-lines.
  - drd\_reset = 1
  - aresetn\_h = 0
  - aresetn\_p = 0Set below external inputs to “1” to activate these “SuspendM” lines.
  - drd\_suspendm\_sel
  - hi\_suspendm\_sel
  - pi\_suspendm\_sel
2. Set below external inputs to the value to deassert these reset-lines.
  - drd\_reset = 0
  - aresetn\_h = 1
  - aresetn\_p = 1
3. The OTG Application SW sets the below bit of the DRD\_INT\_STA register to “1b”.
  - ID\_CHG\_STA
4. The OTG Application SW sets the below bit of the DRD\_INT\_ENA register to “1b”.
  - ID\_CHG\_ENA
5. The OTG Application SW informs the Peripheral driver of the “insmod” command to enable a driver.
6. The Peripheral driver starts the normal connection-sequence as the peripheral role.

## (2) Role Swapping Function by ID Pin

The ID pin “drd\_id” : “1 (Peripheral role) → 0 (Host role)” or “0 (Host role) → 1 (Peripheral role)”

The USB3DRD supports the below only for the role swapping usage.

Figure 34.4-4 Role Swapping Flowchart in DRD Mode

1. “drd\_id” is changed.
2. “drd\_int” is asserted.
3. The OTG Application SW reads the below bit of the DRD\_INT\_STA register.  
If the ID\_CHG\_STA is read “1”, go to “Step 4”.  
If the ID\_CHG\_STA is read “0”, go to “Step 13”.
4. The OTG Application SW informs both drivers (Host and Peripheral) of the “rmmmod” command to disable a driver.
5. The OTG Application SW sets below reset-bits of the DRD\_CON register to “1”.  
– HOST\_RST  
– PERI\_RST
6. The OTG Application SW reads the below bit of DRD\_STA register.  
If the ID\_STA is read “0”, go to “Step 7”.  
If the ID\_STA is read “1”, go to “Step 10”.
7. The OTG Application SW sets below bits as follows.  
– PERI\_CON : 0  
– HOST\_RST : 0  
– PERI\_RST : 1
8. The OTG Application SW informs the Host driver of the “insmod” command to enable a driver.
9. The Host driver starts the normal connection-sequence including “VBUS ON” as the host role.
10. The OTG Application SW sets below bits as follows.  
– PERI\_CON : 1  
– HOST\_RST : 1  
– PERI\_RST : 0
11. The OTG Application SW informs the Peripheral driver of the “insmod” command to enable a driver.
12. The Peripheral driver starts the normal connection-sequence as the peripheral role.
13. The OTG Application SW executes an another OTG process.

**NOTE**

The Type-C specification defines the following specifications.

Therefore, if Type-C receptacle is used as the USB receptacle, the duration between above sequence “Step 1” and “Step 9” shall be completed until 275 ms.

[“Table 4-29 VBUS and VCONN Timing Parameters” in USB Type-C Spec R2.0 - August 2019 specification]

|                      |                                                               |             |
|----------------------|---------------------------------------------------------------|-------------|
| Duration to VBUS ON  | : (After Source-Connection is completed in Type-C controller) | Max. 275 ms |
| Duration to VBUS OFF | : (After Sink-Disconnection is detected in Type-C controller) | Max. 650 ms |

### 34.4.6.2 Battery Charging Function

The USB3DRD supports the Battery Charging function of both the Charging Port device (A-device) and the Portable device (B-device).

#### (1) Charging Port Device (A-Device)

The USB3DRD supports the Charging Port's functions which are defined in the Battery Charging Specification Revision 1.2.

The Battery Charging function supplies more current from VBUS than the current specified in the USB specification.

The USB3DRD's A-device supports the following modes.

- Standard Downstream Port (SDP)
- Charging Downstream Port (CDP)
- Dedicated Charging Port (DCP)

These functions are controlled by the Host role's registers in the Host Controller-portion.

When the user uses the battery charging function, the user can select one of BC modes by setting BC\_MODE\_P1 field of Battery Charging Control Register (BCCTRL) in the Host Controller-portion.

#### (2) Portable Device (B-Device)

The USB3DRD supports the Portable device's functions which are defined in the Battery Charging Specification Revision 1.2.

The USB3DRD supports the following modes of portable device.

- Standard Downstream Port (SDP) Mode
- Charging Downstream Port (CDP) Mode
- Dedicated Charging Port (DCP) Mode

The USB3DRD also supports the following function of portable device.

- Data Contact Detect (DCD)

When the B-device connects to the A-device, it is allowed to draw current from A-device and start charging until the process of device connection is valid with Dead Battery Provision which is defined in the Battery Charging Specification Revision 1.2.

Then the B-device can detect the settable A-device's Battery Charging Mode that is compliant with Good Battery Algorithm in the Battery Charging Specification Revision 1.2.

These functions are controlled by DRD registers in the USB3DRD.

Therefore, it describes how to implement these functions in this sub-sections.

**(a) Pre Sequence**

Before starting the Battery Charging functions in B-device, the user shall access and confirm the following bits. Otherwise the Battery Charging functions are terminated.

- DRD\_CON.PERI\_CON = 1

Figure 34.4-5 Prior Confirmation Flow for the Battery Charging of B-Device

**(b) Weak Battery Algorithm**

As the viewpoint of the battery condition, if the USB peripheral system is not able to execute the USB initialization to connect as the USB device, that USB system is able to operate the Weak Battery Algorithm.

This section describes how to operate the Weak Battery Algorithm in the USB3DRD.

The Weak Battery Algorithm is operated after a detection of “USB-VBUS ON” by the Peripheral driver.

It presupposes that the USB-VBUS is already ON when this flow starts.

Figure 34.4-6 Weak Battery Algorithm Flowchart

1. Start the  $T_{SVLD\_CON\_WKB}$  timer.
  - $T_{SVLD\_CON\_WKB}$  : max. 45 min
2. Set below bits of the DRD\_CON register to “1”
  - VDPSRCEN\_CON
  - IDMSINKEN\_CON

→ The drawable current-level of the USB peripheral system is able to be  $I_{UNIT}$  (100 mA at USB2.0 port / 150 mA at USB3.1 port).
3. If the  $T_{SVLD\_CON\_WKB}$  timer has been expired, go to “Step 4”.  
If the  $T_{SVLD\_CON\_WKB}$  timer has not been expired yet, go to “Step 6”.
4. Set below bits of the DRD\_CON register to “0”.
  - VDPSRCEN\_CON
  - IDMSINKEN\_CON
5. The Peripheral driver judges that the target system is SDP.  
And the drawable current-level of the USB peripheral system shall be  $I_{SUSP}$  (2.5 mA).  
Because, this current-level is the current-level in the case of the “Dead Battery Provision”.  
And the Peripheral driver may set BC\_STA.BCRSLT\_STA to “00b”.
6. If the USB peripheral system has already completed a preparation of “Pull Up” for the USB connection, go to “Step 7”.  
If the USB peripheral system has not completed a preparation of “Pull Up” for the USB connection yet, go to “Step 8”.
7. Set below bits of the DRD\_CON register to “0”.
  - VDPSRCEN\_CON
  - IDMSINKEN\_CON
8. The Peripheral driver reads the below bit of the BC\_STA register.  
If the CHGDET\_STA is read “1”, go to “Step 9”.  
If the CHGDET\_STA is read “0”, go to “Step 3”.
9. Set below bits of the DRD\_CON register to “0”.
  - VDPSRCEN\_CON
  - IDMSINKEN\_CON
10. The Peripheral driver judges that the target system is DCP / CDP.  
And the drawable current-level of the USB peripheral system is able to be  $I_{DEV\_CHG}$  (Max.: 1.5 A).  
And the Peripheral driver may set BC\_STA.BCRSLT\_STA to “00b”.
11. Stop the  $T_{SVLD\_CON\_WKB}$  timer.
12. Start the Good Battery Algorithm.

**(c) Good Battery Algorithm**

This section describes how to operate the Good Battery Algorithm.

The Good Battery Algorithm is operated after completion of the Weak Battery Algorithm or after a detection of USB-VBUS ON by the Peripheral driver. It presupposes that that USB-VBUS is already ON when this flow starts. And it also presupposes that BC\_STA.DCDEN\_STA has already been set to the DCD capability's value of the USB peripheral system.

Figure 34.4-7 Good Battery Algorithm Flowchart (DCD Flow)

1. Start the  $T_{DCD\_TIMEOUT}$  timer.
  - $T_{DCD\_TIMEOUT}$  : min. 300 ms    max. 900 ms
2. The Peripheral driver reads the below bit of the BC\_STA register.
  - If the DCDEN\_STA is read “1”, go to “Step 3”.
  - If the DCDEN\_STA is read “0”, go to “Step 10”.
3. Set below bits of the DRD\_CON register to “1”.
  - IDPSRCEN\_CON
  - DM\_RPD\_CON\_ENA
  - DM\_RPD\_CON
  - CONNECT\_SEL
4. If the  $T_{DCD\_TIMEOUT}$  timer has been expired, go to “Step 9”.
  - If the  $T_{DCD\_TIMEOUT}$  timer has not been expired yet, go to “Step 5”.
5. The Peripheral driver reads the below bit of the DRD\_STA register.
  - If the DP\_STA is read “0”, go to “Step 6”.
  - If the DP\_STA is read “1”, go to “Step 4”.
6. Start the  $T_{DCD\_DBNC}$  timer.
  - $T_{DCD\_DBNC}$  : min. 10 ms
7. If the  $T_{DCD\_DBNC}$  timer has been expired, go to “Step 8”.
  - If the  $T_{DCD\_DBNC}$  timer has not been expired yet, stay in “Step 7” until the  $T_{DCD\_DBNC}$  timer is expired.
8. The Peripheral driver reads the below bit of the DRD\_STA register.
  - If the DP\_STA is read “0”, go to “Step 9”.
  - If the DP\_STA is read “1”, go to “Step 4”.
9. Set below bits of the DRD\_CON register as follows.
  - IDPSRCEN\_CON : 0
  - DM\_RPD\_CON\_ENA : 1
  - DM\_RPD\_CON : 0
  - CONNECT\_SEL : 0
10. If the  $T_{DCD\_TIMEOUT}$  timer has been expired, go to “Step 11”.
  - If the  $T_{DCD\_TIMEOUT}$  timer has not been expired yet, stay in “Step 7” until the DCD timer is expired.
11. Set below bits of the DRD\_CON register to “1”.
  - VDPSRCEN\_CON
  - IDMSINKEN\_CON

Figure 34.4-8 Good Battery Algorithm Flowchart (Primary &amp; Secondary Detection Flow)

12. Start the  $T_{VDPSRC\_ON}$  timer.  
 –  $T_{VDPSRC\_ON}$  : Min. 40 ms
13. If the  $T_{VDPSRC\_ON}$  timer has been expired, go to “Step 14”.  
 If the  $T_{VDPSRC\_ON}$  timer has not been expired yet, stay in “Step 13” until the  $T_{VDPSRC\_ON}$  timer is expired.

14. The Peripheral driver reads the below bit of the BC\_STA register.  
If the CHGDET\_STA is read “1”, go to “Step 15”.  
If the CHGDET\_STA is read “0”, go to “Step 26”.
15. Set below bits of the DRD\_CON register to “0”.  
– VDPSRCEN\_CON  
– IDMSINKEN\_CON
16. If the USB peripheral system has already completed a preparation of “Pull Up” for the USB connection, go to “Step 17”.  
If the USB peripheral system has not completed a preparation of “Pull Up” for the USB connection yet, go to “Step 18”.
17. The Peripheral driver judges that the target system is DCP or CDP.  
And the drawable current-level of the USB peripheral system is able to set to I<sub>DEV\_CHG</sub> (Max.: 1.5 A).  
And the Peripheral driver may set BC\_STA.BCRSLT\_STA to “11b”.
18. Set below bits of the DRD\_CON register to “1”.  
– VDMSRCEN\_CON  
– IDPSINKEN\_CON
19. Start the T<sub>VDMSRC\_ON</sub> timer.  
– T<sub>VDMSRC\_ON</sub> : min. 40 ms
20. If the T<sub>VDMSRC\_ON</sub> timer has been expired, go to “Step 21”.  
If the T<sub>VDMSRC\_ON</sub> timer has not been expired yet, stay in “Step 20” until the T<sub>VDMSRC\_ON</sub> timer is expired.
21. The Peripheral driver reads the below bit of the BC\_STA register.  
If the PRTBLDCPDET\_STA is read “1”, go to “Step 22”.  
If the PRTBLDCPDET\_STA is read “0”, go to “Step 24”.
22. Set below bits of the DRD\_CON register as follows.  
– VDPSRCEN\_CON : 1  
– IDPSINKEN\_CON : 0
23. The Peripheral driver judges that the target system is DCP.  
And the drawable current-level of the USB peripheral system is able to set to I<sub>DEV\_CHG</sub> (Max.: 1.5 A).  
And the Peripheral driver may set BC\_STA.BCRSLT\_STA to “10b”.
24. Set below bits of the DRD\_CON register as follows.  
– VDMSRCEN\_CON : 0  
– IDPSINKEN\_CON : 0
25. The Peripheral driver judges that the target system is CDP.  
And the drawable current-level of the USB peripheral system is able to set to I<sub>DEV\_CHG</sub> (Max.: 1.5 A).  
And the Peripheral driver may set BC\_STA.BCRSLT\_STA to “01b”.
26. Set below bits of the DRD\_CON register to “0”.  
– VDPSRCEN\_CON  
– IDMSINKEN\_CON
27. The Peripheral driver judges that the target system is SDP.  
And the Peripheral driver may set BC\_STA.BCRSLT\_STA to “00b”.

**(d) Post Sequence**

When the Peripheral driver detects the USB-VBUS OFF such as a device disconnection, a subsequent process is operated to prevent from the false-operation in Battery Charging function.

This is operated after a detection of the USB-VBUS OFF by the Peripheral driver, so it presupposes that USB-VBUS has already been set to OFF when this flow starts.

If this operation is called during the Weak or Good Battery Algorithm, it shall put a highest priority on these clearing bits of the DRD\_CON register. Moreover, that interrupted processing is not restarted, and the processing for the Battery Charging function is terminated.

Figure 34.4-9 Register-Bits' Clear for the Battery Charging Function

## 34.4.6.3 Over Current Checking Flow

Figure 34.4-10 Over-Current Checking Flowchart

1. The OTG Application SW sets either DRD\_CON.PERI\_CON or DRD\_CON.VB\_FORCE\_ENA to “1”.
2. The OTG Application SW sets the below bit of the DRD\_CON register to “1”.
  - VB\_CON
3. If the OTG Application SW reports that interrupt-event, go to “Step 4”.  
If the OTG Application SW reports that interrupt-event, go to “Step 10”.
4. The OTG Application SW reads DRD\_INT\_STA.OC\_CHG\_STA and DRD\_STA.OC\_STA.  
If both of these two bits are set to “1”, go to “Step 5”.  
If an either bit is set to “0”, go to “Step 9”.
5. The OTG Application SW sets the below bit of the DRD\_CON register to “0”.
  - VB\_CON
6. The OTG Application SW sets below register-bits as follows.
  - DRD\_INT\_STA.OC\_CHG\_STA : 1
  - DRD\_INT\_ENA.OC\_CHG\_ENA : 0
7. The OTG Application SW executes the “Over Current process”.
8. The OTG Application SW sets the below bit of the DRD\_INT\_ENA register to “1”.
  - DRD\_INT\_ENA.OC\_CHG\_ENA
9. The OTG Application SW executes an another OTG process.
10. The OTG Application SW considers how to set DRD\_CON.VB\_CON.  
If it is OK that VB\_CON is set to “0”, go to “Step 11”.  
If the VB\_CON is kept to be set to “1”, go to “Step 3”.
11. The OTG Application SW sets the below bit of the DRD\_CON register to “0”.
  - VB\_CON

#### 34.4.6.4 Control of SuspendM Signal

SuspendM is the UTMI+ interface signal. This signal controls the current-situation of USB2.0 PHY. And this signal also controls the output of UTMI clock signal.

If SuspendM is set to the high level, UTMI clock signal is supplied by USB2.0 PHY.

If SuspendM is set to the low level, UTMI clock signal is stopped to be supplied by USB2.0 PHY.

The SuspendM signal is a OR of following three signals. That is, actual SuspendM signal will be asserted to low only when all of following three signals are asserted.

- SuspendM signal from Host Controller.
- SuspendM signal from Peripheral Controller.
- SuspendM signal from DRD Controller. (Value specified to DRD\_CON.U2\_SUSPEND\_CON)

SuspendM outputs “0b” during asserting reset.

## 34.5 USB3.1 Gen1 Host Controller (USB3HOST)

### 34.5.1 Introduction

The USB3.1 Gen1 Host Controller (USB3HOST) complies with the Universal Serial Bus (USB) 3.1 Specification.

#### 34.5.1.1 Features

The functions of the USB3HOST are outlined below.

##### (1) USB Functions

The USB3HOST is compliant with *the Universal Serial Bus 3.1 Specification Revision 1.0 and ECNs* approved in June 27, 2017.

- Supports 1 downstream USB receptacles
  - Number of SS ports: 1
  - Number of HS or FS or LS ports: 1
- Supports all USB3.1 Gen1 bus-speeds: Super Speed (5 Gbps), High Speed (480 Mbps), Full Speed (12 Mbps), and Low Speed (1.5 Mbps).
- Supports all transfer-types : Control, Bulk, Interrupt, Isochronous, and these split-transactions.
- Supports Power Control and Over Current Detection.
- Implements the following USB2.0 ECNs USB 2.0 Link Power Management Addendum and LPM functions that are compliant with the xHCI specification.
  - *USB 2.0 Link Power Management Addendum Engineering Change Notice* to the USB 2.0 specification as of July 16, 2007
  - Errata for USB 2.0 ECN: Link Power Management (LPM) - 7/2007 as of October 11, 2011

##### (2) Battery Charging Functions

The USB3HOST supports the following functions that are compliant with *the Battery Charging Specification Revision 1.2*.

- The USB3HOST supports the following modes of chargeable port devices.
  - Standard Downstream Port (SDP) Mode
  - Charging Downstream Port (CDP) Mode
  - Dedicated Charging Port (DCP) Mode

### (3) xHCI Capabilities

The USB3HOST has the following capabilities that are compliant with *the eXtensible Host Controller Interface for the Universal Serial Bus Specification Revision 1.1*.

- Supports 64-bit address capability
- xHCI Host Capability
  - Number of Device Slots (MaxSlots): 32
  - Number of Total Endpoints: 64
  - Number of Event Ring Segment Tables (ERST Max): 2(1)
  - Supported Page Size: 4 Kbytes
  - Context Size (CSZ): 64 bytes(1)
  - Number of Interrupter (MaxIntrs): 1
  - Number of Stream IDs (MaxPSASize): 65536(15)
  - Supports Primary Stream Array
  - Supports the USB Legacy Support.
  - Supports the Hardware LPM Capability.
  - Supports Best Effort Service Latency (BESL) LPM Capability.

### (4) Clock Control

The USB3HOST has the following clock and PLL control functions.

- Clock gating: Enables/disables clock gating to applicable functional sub-blocks depending on the USB state.
- PLL control: Enables/disables PLLs for USB2.0 and USB3.1 depending on their USB states.

## 34.5.2 Interrupts

### 34.5.2.1 Interrupt Diagram

In the USB3HOST, the elements of interrupt are notified by the following layered structure.

INTSTS register is not implemented in any FFs.

This register is a read-only register (monitor register).

Figure 34.5-1 USB3HOST Interrupts Structure

### 34.5.2.2 Interrupt Sources

The USB3HOST has the following interrupt sources.

Table 34.5-1 USB3HOST Interrupt Source Information

| Interrupt Name | Type of Notification | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### 34.5.3 Register Specification

Registers in the USB3HOST are composed of the following register groups.

- xHCI compliant registers
  - Host Controller Capability Registers
  - Host Controller Operational Registers
  - Port Register Sets in Host Controller Registers
  - xHCI Extended Capabilities
  - Host Controller Runtime Registers
  - Doorbell Registers
- USB3HOST's specific registers
  - Core Control and Status Registers
  - Battery Charging Register

aclk is supplied to the USB3HOST from CPG, when the user reads or writes a valid value from/to these registers.

When the situations below occurred, the USB3HOST replies "SLVERR" to the AXI interconnect.

[Conditions in which the USB3HOST replies "SLVERR"]

- The case of access to the Renesas private registers in the register group "Renesas Private Registers".
- The case of access to the related CPC's registers (CRCRL, and CRCRH) or the related HEP's registers (IMAN, IMOD, ERSTSZ, ERSTBAL, ERSTBAH, ERDPL, and ERDPH) in the "Suspend" state of the USB Power State.

For the register base address (<USB\_S0\_base>), see the section of Address Map.

**34.5.3.1 Register Overview**

|                                               |                        |                               |
|-----------------------------------------------|------------------------|-------------------------------|
| Operational Base                              | = CAPLENGTH            | : 0020h                       |

34.5.4 Register Descriptions

The function description of each register is given below.

The prefix (USB\_HOST\_) of the register names is omitted in the register descriptions and the field descriptions in this section.

34.5.4.1 Host Controller Capability Registers

(1) Capability Register Length and Interface Version Number Register (USB\_HOST\_CAPLENGTH\_HCIVERSION)

This register indicates the capability register length and the interface version number.

Table 34.5-10 USB\_HOST\_CAPLENGTH\_HCIVERSION Register Contents

| Bit Position | Bit Name   | Description                                                                                                                                                                                                                                                                                                    |
|--------------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 16     | HCIVERSION | This is a two-byte register containing a BCD encoding of the xHCI specification revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision.<br>(Ex) 0110h corresponds to xHCI version 1.1. |
| 15 to 8      | —          | Reserved                                                                                                                                                                                                                                                                                                       |
| 7 to 0       | CAPLENGTH  | This register is used as an offset to add to register base to find the beginning of the Operational Register Space.                                                                                                                                                                                            |

**(2) Structural Parameters 1 Register (USB\_HOST\_HCSPARAMS1)**

This register is the structural parameter register.

**Access Size:** 32 bits

**Address(es):** <USB\_S0\_base> + 0004h

**Initial Value:** 0200\_0120h

| Bit           | 31                     | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23                     | 22 | 21 | 20 | 19 | 18                     | 17 | 16 |

|--------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 24     | Number of Ports        | This field specifies the maximum Port Number value, i.e. the highest numbered Port Register Sets that are addressable in the Operational Register Space. Valid values are in the range of 1h to FFh. The value in this field shall reflect the maximum Port Number value assigned by an xHCI Supported Protocol Capability, described in section 7.2 of xHCI Specification. Software shall refer to these capabilities to identify whether a specific Port Number is valid, and the protocol supported by the associated Port Register Set. |
| 23 to 19     | —                      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 18 to 8      | Number of Interrupters | This field specifies the number of Interrupters implemented on this host controller. Each Interrupter may be allocated to MSI or MSI-X vector and controls its generation and moderation. The value of this field determines how many Interrupter Register Sets are addressable in the Runtime Register Space. Valid values are in the range of 1h to 400h. A 0h in this field is undefined                                                                                                                                                 |
| 7 to 0       | Number of Device Slots | This field specifies the maximum number of Device Context Structures and Doorbell Array entries this host controller can support. Valid values are in the range of 1 to 255. The value of 0b is reserved.                                                                                                                                                                                                                                                                                                                                   |

**(3) Structural Parameters 2 Register (USB\_HOST\_HCSPARAMS2)**

Table 34.5-12 USB\_HOST\_HCSPARAMS2 Register Contents

| Bit Position | Bit Name                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 27     | Max Scratchpad Buffers (Max Scratchpad Bufs Lo) | Default = implementation dependent. Valid values for Max Scratchpad Buffers (Hi and Lo) are 0 to 1023. This field indicates the lower-order 5 bits of the number of Scratchpad Buffers system software reserves for the xHC.                                                                                                                                                                                                                                                                                                                                                                                                             |
| 26           | Scratchpad Restore (SPR)                        | Default = implementation dependent. If Max Scratchpad Buffers is greater than 0 then this flag indicates whether the xHC uses the Scratchpad Buffers for saving state when executing Save and Restore State operations. If Max Scratchpad Buffers is = 0, then this flag is 0. The value 1 indicates that the xHC requires the integrity of the space for the Scratchpad Buffer to be maintained across power events. The value 0 indicates that the space for the Scratchpad Buffer can be freed and reallocated between power events.                                                                                                  |
| 25 to 21     | Max Scratchpad Buffers (Max Scratchpad Bufs Hi) | Default = implementation dependent. This field indicates the higher-order 5 bits of the number of Scratchpad Buffers system software reserves for the xHC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 20 to 8      | —                                               | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 7 to 4       | Event Ring Segment Table Max (ERST Max)         | Default = implementation dependent. Valid values are 0 to 15. This field determines the maximum value supported by the Event Ring Segment Table Base Size registers, where: The maximum number of Event Ring Segment Table entries = 2 <sup>ERST Max</sup> . e.g. if the ERST Max = 7, then the xHC Event Ring Segment Table(s) supports up to 128 entries, 15 then 32K entries, etc.                                                                                                                                                                                                                                                    |
| 3 to 0       | Isochronous Scheduling Threshold (IST)          | Default = implementation dependent. The value in this field indicates to system software the minimum distance (in time) that it is required to stay ahead of the host controller while adding TRBs, in order to have the host controller process them at the correct time. The value shall be specified in terms of number of frames/microframes. If bit [3] of the IST is cleared to 0, software can add a TRB no later than IST[2:0] Microframes before that TRB is scheduled to be executed. If bit [3] of the IST is set to 1, a TRB is added by software no later than IST[2:0] Frames before that TRB is scheduled to be executed. |

(4) Structural Parameters 3 Register (USB\_HOST\_HCSPARAMS3)

This register is the structural parameter register 3.

Access Size: 32 bits  
Address(es): <USB\_S0\_base> + 000Ch  
Initial Value: 0000\_0000h

Table 34.5-13 USB\_HOST\_HCSPARAMS3 Register Contents

| Bit Position | Bit Name               | Description                                                                                                                                                                                                                                                              |
|--------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 16     | U2 Device Exit Latency | Worst case latency to transition from U2 to U0. Applies to all root hub ports.<br>The following are permissible values:<br>0000h: Zero<br>0001h: Less than 1 us<br>0002h: Less than 2 us<br> <br>07FFh: Less than 2027 us<br>0800h to FFFFh: Reserved                    |
| 15 to 8      | —                      | Reserved                                                                                                                                                                                                                                                                 |
| 7 to 0       | U1 Device Exit Latency | Worst case latency to transition a root hub Port Link State (PLS) from U1 to U0. Applies to all root hub ports.<br>The following are permissible values:<br>00h: Zero<br>01h: Less than 1 us<br>02h: Less than 2 us<br> <br>0Ah: Less than 10 us<br>0Bh to FFh: Reserved |

**(5) Capability Parameter 1 Register (USB\_HOST\_HCCPARAMS1)**

This register is the capability parameter register.

**Access Size:** 32 bits

**Address(es):** <USB\_S0\_base> + 0010h

**Initial Value:** 0140\_FE8Ch

Table 34.5-14 USB\_HOST\_HCCPARAMS1 Register Contents (1/2)

| Bit Position | Bit Name                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 16     | xHCI Extended Capabilities Pointer (xECP)      | This field indicates the existence of a capabilities list. The value of this field indicates a relative offset, in 32-bit words, from Base to the beginning of the first extended capability.<br>For example, using the offset of Base is 1000h and the xECP value of 0068h, we can calculate the following effective address of the first extended capability:<br>$1000h + (0068h \ll 2) \rightarrow 1000h + 01A0h \rightarrow 11A0h$ |
| 15 to 12     | Maximum Primary Stream Array Size (MaxPSASize) | This field identifies the maximum size Primary Stream Array that the xHC supports. The Primary Stream Array size = $2^{\text{MaxPSASize}+1}$ . Valid MaxPSASize values are 0 to 15, where 0 indicates that streams are not supported                                                                                                                                                                                                   |
| 11           | Contiguous Frame ID Capability (CFC)           | This flag indicates that the host controller implementation is capable of matching the Frame ID of consecutive Isoch TDs.                                                                                                                                                                                                                                                                                                              |
| 10           | Stopped EDTLA Capability (SEC)                 | This flag indicates that the host controller implementation Stream Context supports a Stopped EDTLA field. Stopped EDTLA Capability support (i.e. SEC = '1') shall be mandatory for all xHCI 1.1 compliant xHCs.                                                                                                                                                                                                                       |
| 9            | Stopped Short Packet Capability (SPC)          | This flag indicates that the host controller implementation is capable of generating a Stopped Short Packet Completion Code.                                                                                                                                                                                                                                                                                                           |
| 8            | Parse All Event Data (PAE)                     | This flag indicates whether the host controller implementation Parses all Event Data TRBs while advancing to the next TD after a Short Packet, or it skips all but the first Event Data TRB. A 1 in this bit indicates that all Event Data TRBs are parsed. A 0 in this bit indicates that only the first Event Data TRB is parsed.                                                                                                    |
| 7            | No Secondary SID Support (NSS)                 | This flag indicates whether the host controller implementation supports Secondary Stream IDs. A 1 in this bit indicates that Secondary Stream ID decoding is not supported. A 0 in this bit indicates that Secondary Stream ID decoding is supported.                                                                                                                                                                                  |
| 6            | Latency Tolerance Messaging Capability (LTC)   | This flag indicates whether the host controller implementation supports Latency Tolerance Messaging (LTM). A 1 in this bit indicates that LTM is supported. A 0 in this bit indicates that LTM is not supported.                                                                                                                                                                                                                       |
| 5            | Light HC Reset Capability (LHRC)               | This flag indicates whether the host controller implementation supports a Light Host Controller Reset. A 1 in this bit indicates that Light Host Controller Reset is supported. A 0 in this bit indicates that Light Host Controller Reset is not supported. The value of this flag affects the functionality of the Light Host Controller Reset (LHCRST) flag in the USBCMD register.                                                 |

Table 34.5-14 USB\_HOST\_HCCPARAMS1 Register Contents (2/2)

| Bit Position | Bit Name                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4            | Port Indicators (PIND)              | This bit indicates whether the xHC root hub ports support port indicator control. When this bit is 1, the port status and control registers include a readable/writeable field for controlling the state of the port indicator.                                                                                                                                                                                                                                                                                                                                                                                                 |
| 3            | Port Power Control (PPC)            | This flag indicates whether the host controller implementation includes port power control. A 1 in this bit indicates the ports have port power switches. A 0 in this bit indicates the port do not have port power switches. The value of this flag affects the functionality of the PP flag in each port status and control register.                                                                                                                                                                                                                                                                                         |
| 2            | Context Size (CSZ)                  | If this bit is set to 1, then the xHC uses 64 byte Context data structures. If this bit is cleared to 0, then the xHC uses 32 byte Context data structures.<br><br><i>Note: This flag does not apply to Stream Contexts</i>                                                                                                                                                                                                                                                                                                                                                                                                     |
| 1            | BW Negotiation Capability (BNC)     | This flag identifies whether the xHC has implemented the Bandwidth Negotiation.<br>Values for this flag have the following interpretation:<br>0b: BW Negotiation is not implemented.<br>1b: BW Negotiation is implemented.                                                                                                                                                                                                                                                                                                                                                                                                      |
| 0            | 64-bit Addressing Capability (AC64) | This flag documents the addressing range capability of this implementation. The value of this flag determines whether the xHC has implemented the higher-order 32 bits of a 64-bit register and data structure pointer fields.<br>Values for this flag have the following interpretation:<br>0b: 32-bit address memory pointers are implemented<br>1b: 64-bit address memory pointers are implemented<br>If 32-bit address memory pointers are implemented, the xHC ignores the higher-order 32 bits of a 64-bit data structure pointer fields, and system software ignores the higher-order 32 bits of a 64-bit xHC registers. |

(6) Doorbell Offset Register (USB\_HOST\_DBOFF)

This register indicates the doorbell array offset.

Access Size: 32 bits  
Address(es): <USB\_S0\_base> + 0014h  
Initial Value: 0000\_0700h

|               |                       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Table 34.5-15 USB\_HOST\_DBOFF Register Contents

| Bit Position | Bit Name              | Description                                                                                                                                                                                                         |
|--------------|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 2      | Doorbell Array Offset | Default = implementation dependent. This field defines the offset in Dwords of the base address of the Doorbell Array from main base address (i.e. the base address of the xHCI Capability register address space). |
| 1, 0         | —                     | Reserved                                                                                                                                                                                                            |

(7) Runtime Register Space Offset Register (USB\_HOST\_RSTOFF)

This register indicates the 32-byte offset of the xHCI Runtime Registers from the Base.

Access Size: 32 bits  
Address(es): <USB\_S0\_base> + 0018h  
Initial Value: 0000\_0600h

|               |                               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

|--------------|------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 6      | —                                                                      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 5            | Configuration Information Capability (CIC)                             | This bit indicates if the xHC supports extended Configuration Information. When this bit is 1b, the Configuration Value, Interface Number, and Alternate Setting fields in the Input Control Context are supported. When this bit is 0b, the extended Input Control Context fields are not supported.                                                                                                                                            |
| 4            | Large ESIT Payload Capability (LEC)                                    | This bit indicates whether the xHC supports ESIT Payloads greater than 48K bytes. When this bit is 1b, ESIT Payloads greater than 48K bytes are supported. When this bit is 0b, ESIT Payloads greater than 48K bytes are not supported.                                                                                                                                                                                                          |
| 3            | Compliance Transition Capability (CTC)                                 | This bit indicates whether the xHC USB3 Root Hub ports support the Compliance Transition Enabled (CTE) flag. When this bit is 1b, transition of the port state machine of a USB3 Root Hub to the Compliance substate shall be explicitly enabled by software. When this bit is 0b, transition of the port state machine of a USB3 Root Hub to the Compliance substate are automatically enabled.                                                 |
| 2            | Force Save Context Capability (FSC)                                    | This bit indicates whether the xHC supports the Force Save Context Capability. When this bit is 1b, the Save State operation shall save any cached Slot, Endpoint, Stream or other Context information to memory.                                                                                                                                                                                                                                |
| 1            | Configure Endpoint Command Max Exit Latency Too Large Capability (CMC) | This bit indicates whether a Configure Endpoint Command is capable of generating a Max Exit Latency Too Large Capability Error. When this bit is 1b, a Max Exit Latency Too Large Capability Error can be returned by a Configure Endpoint Command. When this bit is 0b, a Max Exit Latency Too Large Capability Error shall not be returned by a Configure Endpoint Command. This capability is enabled by the CME flag in the USBCMD register. |
| 0            | U3 Entry Capability (U3C)                                              | This bit indicates whether the xHC Root Hub ports support port Suspend Complete notification. When this bit is 1b, PLC shall be asserted on any transition of PLS to the U3 State.                                                                                                                                                                                                                                                               |

### 34.5.4.2 Host Controller Operational Registers

#### (1) USB Command Register (USB\_HOST\_USBCMD)

This register issues USB commands.

**Access Size:** 32 bits

**Address(es):** <USB\_S0\_base> + 0020h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Bit Position | Bit Name                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 14     | —                                   | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 13           | CEM Enable (CME)                    | When set to 1, a Max Exit Latency Too Large Capability Error can be returned by a Configure Endpoint Command. When cleared to 0b, a Max Exit Latency Too Large Capability Error shall not be returned by a Configure Endpoint Command. This bit is Reserved if CMC = '0'.                                                                                                                                                                                                                                                                                |
| 12           | Stopped – Short Packet Enable (SPE) | When set to 1, the xHC can generate a Stopped Short Packet Completion Code. This bit is Reserved if SPC = '0'.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 11           | Enable U3 MFINDEX Stop (EU3S)       | Default = 0. When set to 1, the xHC can stop the MFINDEX counting action if all Root Hub ports are in the U3, Disconnected, Disabled, or Powered-off state. When cleared to 0, the xHC can stop the MFINDEX counting action if all Root Hub ports are in the Disconnected, Disabled, Training, or Powered-off state. The USB3HOST does not implement this function.                                                                                                                                                                                      |
| 10           | Enable Wrap Event (EWE)             | Default = 0. When set to 1, the xHC generates a MFINDEX Wrap Event every time the MFINDEX register transitions from 0_3FFFh to 0_0000h. When cleared to 0, no MFINDEX Wrap Events are generated                                                                                                                                                                                                                                                                                                                                                          |
| 9            | Controller Restore State (CRS)      | Default = 0. When set to 1, and HCHalted (HCH) = 1, then the xHC performs a Restore State operation and restores its internal state. When set to 1 and Run/Stop (R/S) = 1 or HCHalted (HCH) = 0, or when cleared to 0, no Restore State operation is performed. This flag always returns 0 when read. Refer to the Restore State Status (RSS) flag in the USBSTS register for information on Restore State completion. Note that undefined behavior can occur if a Restore State operation is initiated while Save State Status (SSS) = 1.               |
| 8            | Controller Save State (CSS)         | Default = 0. When 1 is written by software and HCHalted (HCH) = 1, then the xHC saves any internal state that can be restored by a subsequent Restore State operation. When 1 is written by software and HCHalted (HCH) = 0, or 0 is written, no Save State operation is performed. This flag always returns 0 when read. Refer to the Save State Status (SSS) flag in the USBSTS register for information on Save State completion. Note that undefined behavior can occur if a Save State operation is initiated while Restore State Status (RSS) = 1. |

|--------------|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7            | Light Host Controller Reset (LHCRST) | The Default = Controller Light HC Reset Capability (LHRC) bit in the HCCPARAMS1 register is formed on completion of the save state. Note that the xHC does not affect the state of the ports. When system software reads this bit, the value 0 indicates that the Light Host Controller Reset has been completed and it is safe for software to re-initialize the xHC. The value 1 indicates that the Light Host Controller Reset has not yet been completed. If not implemented, reading of this flag always returns a "0".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 6 to 4       | —                                    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 3            | Host System Error Enable (HSEE)      | Default = 0. When this bit is 1, and the HSE bit in the USBSTS register is 1, the xHC asserts the out-of-band error signal for the host. The signal is acknowledged by software clearing the HSE bit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 2            | Interrupter Enable (INTE)            | Default = 0. This bit provides system software with a means of enabling or disabling the host system interrupts generated by Interrupters. When this bit is 1, then Interrupter host system interrupt generation is allowed, e.g. the xHC issues an interrupt at the next interrupt threshold if the host system interrupt mechanism (e.g. MSI, MSI-X, etc.) is enabled. The interrupt is acknowledged by a host system interrupt specific mechanism.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 1            | Host Controller Reset (HCRST)        | Default = 0. This control bit is used by software to reset the host controller. The effects of this bit on the xHC and the Root Hub registers are similar to those of a Chip Hardware Reset. When 1 is written to this bit by software, the Host Controller resets its internal pipelines, timers, counters, state machines, etc. to their initial values. Any transaction currently in progress on the USB is immediately terminated. A USB reset is not driven on USB2 downstream ports, however a Hot or Warm Reset is initiated on USB3 Root Hub downstream ports. PCI Configuration registers are not affected by this reset. All operational registers, including port registers and port state machines are set to their initial values. Software reinitializes the host controller in order to return the host controller to an operational state. This bit is cleared to 0 by the Host Controller when the reset process is complete. Software cannot terminate the reset process early by writing 0 to this bit and does not write any xHC Operational or Runtime registers until while HCRST is 1. Note that the completion of the xHC reset process is not gated by the Root Hub port reset process. This bit is not set to 1 by software when the HCHalted (HCH) bit in the USBSTS register is 0. Attempting to reset an actively running host controller can result in undefined behavior. |
| 0            | Run/Stop (R/S)                       | Default = 0. 1 = Run. 0 = Stop. When set to 1, the xHC proceeds with execution of the schedule. The xHC continues execution as long as this bit is set to 1. When this bit is cleared to 0, the xHC completes any current or queued commands or TDs, and any USB transactions associated with them, then halt. The xHC halts within 16 ms. After the Run/Stop bit is cleared by software if the above conditions have been met. The HCHalted (HCH) bit in the USBSTS register indicates when the xHC has finished its pending pipelined transactions and has entered the stopped state. 1 is not written by software to this flag unless the xHC is in the Halted state (i.e. HCH in the USBSTS register is 1). Doing so can yield undefined results. Writing 0 to this flag when the xHC is in the Running state (i.e. HCH = 0) and any Event Rings are in the Event Ring Full state can result in lost events.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**(2) USB Status Register (USB\_HOST\_USBSTS)**

This register is the USB status register.

**Access Size:** 32 bits

**Address(es):** <USB\_S0\_base> + 0024h

**Initial Value:** 0000\_0001h

Table 34.5-19 USB\_HOST\_USBSTS Register Contents (1/2)

| Bit Position | Bit Name                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 13     | —                           | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 12           | Host Controller Error (HCE) | Default = 0. 0 = No internal xHC error conditions exist and 1 = Internal xHC error condition. This flag shall be set to indicate detection of an internal error condition, which requires a reset and reinitialization of the xHC by software.                                                                                                                                                                                                                                                |
| 11           | Controller Not Ready (CNR)  | Default = 0. 0 = Ready and 1 = Not Ready. Doorbell or Operational register of the xHC, other than the USBSTS register, are not written by software while CNR = 0. This flag is set by the xHC after a Chip Hardware Reset and cleared when the xHC is ready to begin accepting register writes. This flag remains cleared (0) until the next Chip Hardware Reset.                                                                                                                             |
| 10           | Save/Restore Error (SRE)    | Default = 0. If an error occurs during a Save or Restore operation, this bit is set to 1. This bit is cleared to 0 when a Save or Restore operation is initiated or when written with 1.                                                                                                                                                                                                                                                                                                      |
| 9            | Restore State Status (RSS)  | Default = 0. When the Controller Restore State (CRS) flag in the USBCMD register is written with 1, this bit is set to 1 and remains 1 while the xHC restores its internal state. When the Restore State operation is complete, this bit is cleared to 0.                                                                                                                                                                                                                                     |
| 8            | Save State Status (SSS)     | Default = 0. When the Controller Save State (CSS) flag in the USBCMD register is written with 1, this bit is set to 1 and remains 1 while the xHC saves its internal state. When the Save State operation is complete, this bit is cleared to 0.                                                                                                                                                                                                                                              |
| 7 to 5       | —                           | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 4            | Port Change Detect (PCD)    | Default = 0. The xHC sets this bit to 1 when a bit of any port has a state transition from 0 to 1. This bit can be maintained in the Aux Power as well. Alternatively, loading this bit with the OR of all of the PORTSC change bits on a D3 to D0 transition of the xHC is also acceptable. This bit provides system software an efficient means of determining if there has been Root Hub port activity.<br>It is cleared by writing 1b. Writing 0b has no effect.                          |
| 3            | Event Interrupt (EINT)      | Default = 0. The xHC sets this bit to 1 in response to a transition of the Interrupt Pending (IP) bit from any interrupt source from 0 to 1. Software that uses EINT clears it prior to clearing any IP flags. A race condition can occur if software clears the IP flags then clears the EINT flag, and another IP 0 to 1 transition occurs between these operations. In this case the new transition of the IP bit shall be lost.<br>It is cleared by writing 1b. Writing 0b has no effect. |

Table 34.5-19 USB\_HOST\_USBSTS Register Contents (2/2)

| Bit Position | Bit Name                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2            | Host System Error (HSE) | Default = 0. The xHC sets this bit to 1 when a serious error is detected, either internal to the xHC or during a host system access involving the xHC module. In a PCI system, conditions that lead to this bit being set to 1 include a PCI Parity error, PCI Master Abort, and PCI Target Abort. When this error occurs, the xHC clears the Run/Stop (R/S) bit in the USBCMD register to prevent further execution of the scheduled TDs. If the HSEE bit in the USBCMD register is 1, the xHC also asserts the out-of-band error signal to the host. It is cleared by writing 1b. Writing 0b has no effect. |
| 1            | —                       | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 0            | HCHalted (HCH)          | Default = 1b. This bit is 0b whenever the Run/Stop (R/S) bit is set to 1b. The xHC sets this bit to 1b after it has stopped executing as a result of the Run/Stop (R/S) bit being cleared to 0b, either by software or by the xHC hardware (e.g. internal error). If this bit is 1b, then SOFs, microSOFs, or Isochronous Timestamp Packets (ITP) is not generated by the xHC, and any received Transaction Packet is dropped.                                                                                                                                                                                |

(3) Page Size Register (USB\_HOST\_PAGESIZE)

This register indicates the page size supported by the xHC implementation.

| 15 to 0      | Page Size | Default = Implementation defined. This field defines the page size supported by the xHC implementation. This xHC supports a page size of 2 <sup>n+12</sup> if bit n is set. For example, if bit 0 is set, the xHC supports 4-Kbyte page sizes. For a Virtual Function, this register reflects the page size selected in the System Page Size field of the SR-IOV Extended Capability structure. For the Physical Function 0, this register reflects the implementation dependent default xHC page size. Various xHC resources reference PAGESIZE to describe their minimum alignment requirements. The maximum possible page size is 128M. |

(4) Device Notification Control Register (USB\_HOST\_DNCTRL)

This register controls the device notification.

Access Size: 32 bits  
Address(es): <USB\_S0\_base> + 0034h  
Initial Value: 0000\_0000h

|               |                     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Table 34.5-22 USB\_HOST\_CRCRL Register Contents

| Bit Position | Bit Name                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 6      | Command Ring Pointer Low   | Default = 0. This field defines lower-order bits of the initial value of the 64-bit Command Ring Dequeue Pointer. Writing to this field is ignored when Command Ring Running (CRR) = 1. In writing to the CRCR (combination of CRCRL and CRCRH) while the Command Ring is stopped (CRR = 0), the value of this field is used to fetch the first Command TRB the next time writing to the Host Controller Doorbell register proceeds with the DB Reason field set to Host Controller Command. If the CRCR is not written while the Command Ring is stopped (CRR = 0), then the Command Ring begins fetching Command TRBs at the current value of the internal xHC Command Ring Dequeue Pointer. Reading this field always returns 0. |
| 5, 4         | —                          | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 3            | Command Ring Running (CRR) | Default = 0. This flag is set to 1 if the Run/Stop (R/S) bit is 1 and the Host Controller Doorbell register is written with the DB Reason field set to Host Controller Command. It is cleared to 0 when the Command Ring is "stopped" after writing 1 to the Command Stop (CS) or Command Abort (CA) flags, or if the R/S bit is cleared to 0.                                                                                                                                                                                                                                                                                                                                                                                      |
| 2            | Command Abort (CA)         | Default = 0. Writing a 1 to this bit immediately terminates the command currently being executed, stops the Command Ring, and generates a Command Completion Event with the Completion Code set to Command Ring Stopped. The next write to the Host Controller Doorbell with DB Reason field set to Host Controller Command shall restart the Command Ring operation. Writing to this flag is ignored by the xHC if Command Ring Running (CRR) = 0. Reading this bit always returns 0.                                                                                                                                                                                                                                              |
| 1            | Command Stop (CS)          | Default = 0. Writing a 1 to this bit stops the operation of the Command Ring after completion of the command currently being executed, and generates a Command Completion Event with the Completion Code set to Command Ring Stopped and the Command TRB Pointer set to the current value of the Command Ring Dequeue Pointer. The next write to the Host Controller Doorbell with DB Reason field set to Host Controller Command shall restart the Command Ring operation. Writing to this flag is ignored by the xHC if Command Ring Running (CRR) = 0. Reading this bit always returns 0.                                                                                                                                        |
| 0            | Ring Cycle State (RCS)     | This bit identifies the value of the xHC Consumer Cycle State (CCS) flag for the TRB referenced by the Command Ring Pointer. Writing to this flag is ignored if Command Ring Running (CRR) is 1. In case of writing to the CRCR while the Command Ring is stopped (CRR = 0), the value of this flag is used to fetch the first Command TRB the next time writing to the Host Controller Doorbell register proceeds with the DB Reason field set to Host Controller Command. If the CRCR is not written while the Command Ring is stopped (CRR = 0), then the Command Ring begins fetching Command TRBs using the current value of the internal Command Ring CCS flag. Reading this flag always returns 0.                           |

(6) Command Ring Control High Register (USB\_HOST\_CRCRH)

This register defines higher-order bits of the initial value of the 64-bit Command Ring Dequeue Pointer.

Access Size: 32 bits  
Address(es): <USB\_S0\_base> + 003Ch  
Initial Value: 0000\_0000h

Table 34.5-23 USB\_HOST\_CRCRH Register Contents

| Bit Position | Bit Name                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | Command Ring Pointer High | Default = 0. This field defines higher-order bits of the initial value of the 64-bit Command Ring Dequeue Pointer. Writing to this field is ignored when Command Ring Running (CRR) = 1. In case of writing to the CRCR while the Command Ring is stopped (CRR = 0), the value of this field is used to fetch the first Command TRB the next time writing to the Host Controller Doorbell register proceeds with the DB Reason field set to Host Controller Command. If the CRCR is not written while the Command Ring is stopped (CRR = 0) then the Command Ring begins fetching Command TRBs at the current value of the internal xHC Command Ring Dequeue Pointer. Reading this field always returns 0. |

(7) Device Context Base Address Array Pointer Low Register (USB\_HOST\_DCBAAPL)

This register defines lower-order bits of the 64-bit base address of the Device Context Pointer Array.

Access Size: 32 bits  
Address(es): <USB\_S0\_base> + 0050h  
Initial Value: 0000\_0000h

Table 34.5-24 USB\_HOST\_DCBAAPL Register Contents

| Bit Position | Bit Name                                      | Description                                                                                                                                                                                                       |
|--------------|-----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 6      | Device Context Base Address Array Pointer Low | This field defines lower-order bits of the 64-bit base address of the Device Context Pointer Array. A table of address pointers that reference Device Context structures for the devices is attached to the host. |
| 5 to 0       | —                                             | Reserved                                                                                                                                                                                                          |

(8) Device Context Base Address Array Pointer High Register (USB\_HOST\_DCBAAPH)

This register defines higher-order bits of the 64-bit base address of the Device Context Pointer Array.

Access Size: 32 bits  
Address(es): <USB\_S0\_base> + 0054h  
Initial Value: 0000\_0000h

Table 34.5-25 USB\_HOST\_DCBAAPH Register Contents

| Bit Position | Bit Name                                       | Description                                                                                                                                                                                                         |
|--------------|------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | Device Context Base Address Array Pointer High | This field defines higher-order bits of the 64-bit base address of the Device Context Pointer Array. A table of address pointers that reference Device Context structures for the devices are attached to the host. |

**(9) Configure Register (USB\_HOST\_CONFIG)**

This register configures USB3HOST.

**Access Size:** 32 bits

**Address(es):** <USB\_S0\_base> + 0058h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Bit Position | Bit Name                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 10     | —                                      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 9            | Configuration Information Enable (CIE) | When set to 1, the software shall initialize the Configuration Value, Interface Number, and Alternate Setting fields in the Input Control Context when it is associated with a Configure Endpoint Command. When this bit is 0b, the extended Input Control Context fields are not supported.                                                                                                                                                                     |
| 8            | U3 Entry Enable (U3E)                  | When set to 1, the xHC shall assert the PLC flag (1b) when a Root Hub port transitions to the U3 State.                                                                                                                                                                                                                                                                                                                                                          |
| 7 to 0       | Max Device Slots Enabled (MaxSlotsEn)  | Default = 0. This field specifies the maximum number of enabled Device Slots. Valid values are in the range of 0 to MaxSlots. Enabled Devices Slots are allocated contiguously. E.g.) A value of 16 specifies that Device Slots 1 to 16 are active. A value of 0 disables all Device Slots. A disabled Device Slot shall not respond to Doorbell Register references. This field shall not be modified by software if the xHC is running (Run/Stop (R/S) = '1'). |

### 34.5.4.3 Port Register Sets in Host Controller Operational Registers

#### (1) U3P1 Port Status and Control Register (USB\_HOST\_U3P1PORTSC)

This register contains the USB 3.1 port status and control bits.

**Access Size:** 32 bits

**Address(es):** <USB\_S0\_base> + 0420h

**Initial Value:** 0000\_02A0h

| Bit           | 31                           | 30                    | 29 | 28 | 27                                | 26                              | 25                           | 24                       | 23                             | 22                           | 21                      | 20                        | 19                           | 18                               | 17                          | 16                                 |

| 13 to 10     | Port Speed                         | <p>Speed type of USB device connected to the port.</p> <p>This is enabled only when a device is connected to the port. (Current Connect Status is 1) After a port reset, this field indicates the speed of the device connected to the port. If the reset or speed detection fails, this field indicates an unknown speed. When the Current Connect Status changes from 0 to 1, this field indicates an undefined speed.</p> <p>0000b: Undefined speed (before speed detection)<br/>           0001b to 0011b: Reserved<br/>           0100b: SuperSpeed device is attached.<br/>           0101b: SuperSpeed Plus device is attached.<br/>           0110b to 1111b: Reserved</p>                                                                                                                                                                                                                                                                                                                                                               |
| 9            | Port Power (PP)                    | <p>This field reflects a port's logical power state.</p> <p>0b: This port is in the Powered-off state.<br/>           1b: This port is not in the Powered-off state.</p> <p>When the Port Power Control (PPC) bit in the HCCPARAMS1 Register is 1, the xHC has a port power control switch and this bit shows the current state of the switch. (0: off, 1: on)<br/>           When the Port Power Control (PPC) bit in the HCCPARAMS1 Register is set to "0", the xHC has no port power control switch and each port is hard wired to power and not affected by this bit. If an over-current condition is detected at a powered port, the PP bit of each port is changed from 1 to 0. After modifying PP, software shall read PP and confirm that it is reached its target state before modifying it again (page 312 of the xHCI specification). PP flag can be delayed in reflecting this change, (Ex) due to waiting for a port related state machine to complete reset signaling or other operation. (page 315 of the xHCI specification)</p> |

Table 34.5-27 USB\_HOST\_U3P1PORTSC Register Contents (3/4)

| Bit Position | Bit Name                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**(2) U3P1 Port Power Management Status and Control Register (USB\_HOST\_U3P1PORTPMSC)**

This register contains the USB 3.1 port power management status and control bits.

**Access Size:** 32 bits

**Address(es):** <USB\_S0\_base> + 0424h

**Initial Value:** 0000\_0000h

**(3) U3P1 Port Link Info Register (USB\_HOST\_U3P1PORTLI)**

This register indicates the USB 3.1 port link information.

**Access Size:** 32 bits

**Address(es):** <USB\_S0\_base> + 0428h

**Initial Value:** 0000\_0000h

| Bit           | 31               | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23                  | 22 | 21 | 20 | 19                  | 18 | 17 | 16 |

| Bit Position | Bit Name            | Description                                                                                                                                                                                                                                                                                             |
|--------------|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 24     | —                   | Reserved                                                                                                                                                                                                                                                                                                |
| 23 to 20     | Tx Lane Count (TLC) | This field that identifies the number of Transmit Lanes negotiated by the port. This is a "zero-based" value, where 0 to 15 represents Lane Counts of 1 to 16, respectively.<br>This value is valid only when CCS = '1'. TLC shall equal '0' for a simplex Sublink. This core's value is fixed to "0h". |
| 19 to 16     | Rx Lane Count (RLC) | This field that identifies the number of Receive Lanes negotiated by the port. This is a "zero-based" value, where 0 to 15 represents Lane Counts of 1 to 16, respectively.<br>This value is valid only when CCS = '1'. RLC shall equal '0' for a simplex Sublink. This core's value is fixed to "0h".  |
| 15 to 0      | Link Error Count    | This field returns the number of link errors detected by the port. This value shall be reset to '0' by the assertion of a Chip Hardware Reset, HCRST, when PR transitions from '1' to '0', or when CCS = transitions from '0' to '1'.                                                                   |

(4) U3P1 Port Hardware LPM Control Register (USB\_HOST\_U3P1PORTHLPMC)

This register reserved for USB 3.1. The Hardware LPM Control Register is used for USB 2.0 (Section 34.5.4.3(8)).

Access Size: 32 bits  
Address(es): <USB\_S0\_base> + 042Ch  
Initial Value: 0000\_0000h

**(6) U2P1 Port Power Management Status and Control Register (USB\_HOST\_U2P1PORTPMSC)**

This register contains the USB 2.0 port power management status and control bits.

**Access Size:** 32 bits

**Address(es):** <USB\_S0\_base> + 0434h

**Initial Value:** 0000\_0000h

| 31 to 28     | Port Test Control (Test Mode)      | <p>When this field is '0', the port is NOT operating in a test mode. A non-zero value indicates that it is operating in test mode and the specific test mode is indicated by the specific value. A non-zero Port Test Control value is only valid to a port that is in the Powered-Off state (PLS = Disabled). If the port is not in this state, the xHC shall respond with the Port Test Control field set to Port Test Control Error. Refer to section 4.19.6 of xHCI 1.1 specification for the operational model for using these test modes.</p> <p>The encoding of the Test Mode bits for a USB2 protocol port are :</p> <p>0000b: Test mode not enabled<br/> 0001b: Test J_STATE<br/> 0010b: Test K_STATE<br/> 0011b: Test SE0_NAK<br/> 0100b: Test Packet<br/> 0101b: Test FORCE_ENABLE<br/> 0110b to 1110b: Reserved<br/> 1111b: Port Test Control Error</p> <p>Refer to the sections 7.1.20 and 11.24.2.13 of the USB2 spec for more information on Test Modes.</p> |
| 27 to 17     | —                                  | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 16           | Hardware LPM Enable (HLE)          | <p>If this bit is set to '1', then hardware controlled LPM shall be enabled for this port. Refer to section 4.23.5.1.1.1 of xHCI 1.1 specification. If the USB2 Hardware LPM Capability is not supported (HLC = '0') this field shall be RsvdZ. Note the BESL LMP Capability support (i.e. HLE = '1' and BLC = '1') shall be mandatory for all xHCI 1.1 compliant xHCs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 15 to 8      | L1 device Slot                     | <p>System software sets this field to indicate the ID of the Device Slot associated with the device directly attached to the Root Hub port. A value of '0' indicates no device is present. The xHC uses this field to lookup information necessary to generate the LPM Token packet.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 7 to 4       | Best Effort Service Latency (BESL) | <p>System software sets this field to indicate to the recipient device how long the xHC will drive resume if it (the xHC) initiates an exit from L1. The BESL value encoding is defined in Table 13 of xHCI 1.1 specification.</p> <p><i>Note:</i> The BESL field is used by both software and hardware controlled LPM. Refer to section 4.23.5.1.1 of xHCI 1.1 for more information on BESL use. Refer to section 5.2.5 of xHCI 1.1 for information on how DBESL can be used to establish an initial value for BESL.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| 13 to 10     | Best Effort Service Latency Deep (BESLD)    | System software sets this field to indicate to the recipient device how long the xHC will drive resume on an exit from U2.<br>Refer to section 4.23.5.1.1.1 of xHCI 1.1 for more information on BESLD use. The BESLD value encoding is defined in Table 13 of xHCI 1.1. Refer to section 5.2.6 of xHCI 1.1 for information on how DBESLD can be used to establish an initial value for BESLD. |
| 9 to 2       | L1 Timeout                                  | Timeout value for the L1 inactivity timer (LPM Timer). This field shall be set to 00h by the assertion of PR to '1'. Refer to section 4.23.5.1.1.1 of xHCI 1.1 for more information on L1 Timeout operation. The following are permissible values:<br>00h: 128 $\mu$ s (default)<br>01h: 256 $\mu$ s<br>02h: 512 $\mu$ s<br>03h: 768 $\mu$ s<br> <br>FFh: 65.280 ms                           |
| 1, 0         | Host Initiated Resume Duration Mode (HIRDM) | Indicates which HIRD value should be used. The following are permissible values:<br>00b: Initiate L1 using BESL only on timeout. (default)<br>01b: Initiate L1 using BESLD on timeout. If rejected by device, initiate L1 using BESL.<br>10b, 11b: Reserved                                                                                                                                   |

### 34.5.4.4 xHCI Extended Capabilities

#### (1) USB Legacy Supported Protocol Capability

##### (a) USB Legacy Support Capability Register (USB\_HOST\_USBLEGSUP)

USB legacy support capability register.

**Access Size:** 32 bits

**Address(es):** <USB\_S0\_base> + 0500h

**Initial Value:** 0000\_0401h

| Bit           | 31                      | 30 | 29 | 28 | 27 | 26 | 25 | 24                                        | 23            | 22 | 21 | 20 | 19 | 18 | 17 | 16                                             |
|---------------|-------------------------|----|----|----|----|----|----|-------------------------------------------|---------------|----|----|----|----|----|----|------------------------------------------------|
|               | —                       | —  | —  | —  | —  | —  | —  | HC OS<br>Owned<br>Semaph<br>ore<br>(HOOS) | —             | —  | —  | —  | —  | —  | —  | HC<br>BIOS<br>Owned<br>Semaph<br>ore<br>(HBOS) |
| Initial Value | 0                       | 0  | 0  | 0  | 0  | 0  | 0  | 0                                         | 0             | 0  | 0  | 0  | 0  | 0  | 0  | 0                                              |

Table 34.5-35 USB\_HOST\_USBLEGSUP Register Contents

| Bit Position | Bit Name                       | Description                                                                                                                                                          |
|--------------|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 25     | —                              | Reserved                                                                                                                                                             |
| 24           | HC OS Owned Semaphore (HOOS)   | System software sets this bit to request ownership of the xHC. Ownership is obtained when this bit is reads as 1 and the HC BIOS Owned Semaphore bit is reads as 0.  |
| 23 to 17     | —                              | Reserved. These bits are read as 0b. Writing is invalid.                                                                                                             |
| 16           | HC BIOS Owned Semaphore (HBOS) | The BIOS sets this bit to establish ownership of the xHC. System BIOS will set this bit to a 0 in response to a request for ownership of the xHC by system software. |
| 15 to 8      | Next Capability Pointer        | This field indicates the location of the next capability relative to the effective address of the current capability.                                                |
| 7 to 0       | Capability ID                  | Legacy Support                                                                                                                                                       |

**(b) USB Legacy Support Control and Status Register (USB\_HOST\_USBLEGCTLSTS)**

USB legacy support control and status register.

**Access Size:** 32 bits

**Address(es):** <USB\_S0\_base> + 0504h

**Initial Value:** 0000\_0000h

| Bit           | 31               | 30                       | 29                                | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20                              | 19 | 18 | 17 | 16                           |

Table 34.5-36 USB\_HOST\_USBLEGCTLSTS Register Contents (1/2)

| Bit Position | Bit Name                                | Description                                                                                                                                                         |
|--------------|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31           | SMI on BAR (SBA)                        | This bit is set to 1 whenever the Base Address Register (BAR) is written.<br>This bit is fixed to 0b, because the USB3HOST does not have the Base Address Register. |
| 30           | SMI on PCI Command (SPC)                | This bit is set to 1 whenever the PCI Command Register is written.<br>This bit is fixed to 0b, because the USB3HOST does not have the PCI Command Register.         |
| 29           | SMI on OS Ownership Change (SOOC)       | This bit is set to 1 whenever the HC OS Owned Semaphore bit in the USBLEGSUP register transitions from 1 to 0 or 0 to 1.                                            |
| 28 to 21     | —                                       | Reserved                                                                                                                                                            |
| 20           | SMI on Host System Error (SHSE)         | Shadow bit of the Host System Error (HSE) bit in the USBSTS register.                                                                                               |
| 19 to 17     | —                                       | Reserved. These bits are read as 0b. Writing is invalid.                                                                                                            |
| 16           | SMI on Event Interrupt (SEI)            | Shadow bit of Event Interrupt (EINT) bit in the USBSTS register.                                                                                                    |
| 15           | SMI on BAR Enable (SBAE)                | When this bit is 1 and SMI on BAR is 1, then the host controller will issue an SMI.                                                                                 |
| 14           | SMI on PCI Command Enable (SPCE)        | When this bit is 1 and SMI on PCI Command is 1, then the host controller will issue an SMI.                                                                         |
| 13           | SMI on OS Ownership Enable (SOOE)       | When this bit is 1 and the OS Ownership Change bit is 1, the host controller will issue an SMI.                                                                     |
| 12 to 5      | —                                       | Reserved                                                                                                                                                            |
| 4            | SMI on Host System Error Enable (SHSEE) | When this bit is 1 and the SMI on Host System Error bit (below) in this register is 1, the host controller will issue an SMI immediately.                           |
| 3 to 1       | —                                       | Reserved                                                                                                                                                            |

Table 34.5-36 USB\_HOST\_USBLEGCTLSTS Register Contents (2/2)

| Bit Position | Bit Name             | Description                                                                                                                     |
|--------------|----------------------|---------------------------------------------------------------------------------------------------------------------------------|
| 0            | USB SMI Enable (USE) | When this bit is 1 and the SMI on Event Interrupt bit in this register is 1, the host controller will issue an SMI immediately. |

**(2) xHCI Supported Protocol Capability for USB3.1****(a) Offset 00h - xHCI Supported Protocol Capability Field Definitions (USB3.1) Register (USB\_HOST\_U3HCSPC1)**

xHCI supported protocol capability field definitions (USB3.1) register.

**Access Size:** 32 bits

**Address(es):** <USB\_S0\_base> + 0510h

**Initial Value:** 0301\_0802h

Table 34.5-39 USB\_HOST\_U3HCSPC3 Register Contents

| Bit Position | Bit Name                       | Description                                                                                                                                                                                                                                                                                                                                                            |
|--------------|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 28     | Protocol Speed ID Count (PSIC) | This field indicates the number of Protocol Speed ID (PSI) Dwords that the xHCI Supported Protocol Capability data structure contains. If this field is non-zero, then all speeds supported by the protocol shall be defined using PSI Dwords, i.e. no implied Speed ID mappings apply. PSIC value of 0 implies that only the default SuperSpeed bit rate is supported |
| 27 to 25     | Hub Depth (MHD)                | If this field is '0', then the standard USB2 hub depth constraints apply, if this field is > '0', then it indicates the maximum hub depth supported by the USB2 ports.<br>This bit is fixed to 0h in the USB3HOST.                                                                                                                                                     |
| 24 to 16     | —                              | Reserved                                                                                                                                                                                                                                                                                                                                                               |
| 15 to 8      | Compatible Port Count          | This field identifies the number of consecutive Root Hub Ports (starting at the Compatible Port Offset) that support this protocol. Valid values are 1 to MaxPorts                                                                                                                                                                                                     |
| 7 to 0       | Compatible Port Offset         | This field specifies the starting Port Number of Root Hub Ports that support this protocol. Valid values are 1 to MaxPorts.                                                                                                                                                                                                                                            |

(d) Offset 0Ch - xHCI Supported Protocol Capability Field Definitions (USB3.1) Register (USB\_HOST\_U3HCSPC4)

Table 34.5-45 USB\_HOST\_U2HCSPC3 Register Contents

| Bit Position | Bit Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 28     | Protocol Speed ID Count (PSIC)   | This field indicates the number of Protocol Speed ID (PSI) Dwords that the xHCI Supported Protocol Capability data structure contains. If this field is non-zero, then all speeds supported by the protocol shall be defined using PSI Dwords, i.e. no implied Speed ID mappings apply. PSIC value of 0 implies that the default Full-speed, Low-speed, and High-speed bit rates are supported.                                                                                                                                                  |
| 27 to 25     | Hub Depth (MHD)                  | If this field is '0', then the standard USB2 hub depth constraints apply, if this field is > '0', then it indicates the maximum hub depth supported by the USB2 ports.<br>This bit is fixed to 0h in the USB3HOST.                                                                                                                                                                                                                                                                                                                               |
| 24 to 21     | —                                | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 20           | BESL LPM Capability (BLC)        | If this bit is set to 1b, the ports described by this xHCI Supported Protocol Capability shall apply BESL timing to BESL and BESLD fields of the PORTPMSC and PORTHLPMC registers. If this bit is cleared to 0b, the ports described by this xHCI Supported Protocol Capability shall apply HIRD timing to BESL and BESLD fields of the PORTPMSC and PORTHLPMC registers.<br>Note the BESL LPM Capability support (i.e. HLE = '1' and BLC = '1') shall be mandatory for all xHCI 1.1 compliant xHCs.<br>This bit is fixed to 1b in the USB3HOST. |
| 19           | Hardware LPM Capability (HLC)    | If this bit is set to 1b, the ports described by this xHCI Supported Protocol Capability support hardware controlled USB2 Link Power Management.<br>This bit is fixed to 1b in the USB3HOST.                                                                                                                                                                                                                                                                                                                                                     |
| 18           | Integrated Hub Implemented (IHI) | If this bit is cleared to 0b, the Root hub to External xHC port mapping adheres to the default mapping. If this bit is set to 1b, the Root Hub to External xHC port mapping does not adhere to the default mapping, and ACPI or other mechanism is required to define the mapping.<br>This bit is fixed to 0b in the USB3HOST.                                                                                                                                                                                                                   |
| 17           | High-speed Only (HSO)            | If this bit is cleared to 0b, the USB2 ports described by this capability are High-speed only, e.g. the ports do not support Low- or Full-speed operation. High-speed only implementations can introduce a "Tier mismatch".                                                                                                                                                                                                                                                                                                                      |
| 16           | —                                | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 15 to 8      | Compatible Port Count            | This field identifies the number of consecutive Root Hub Ports (starting at the Compatible Port Offset) that support this protocol. Valid values are 1 to MaxPorts.                                                                                                                                                                                                                                                                                                                                                                              |
| 7 to 0       | Compatible Port Offset           | This field specifies the starting Port Number of Root Hub Ports that support this protocol. Valid values are 1 to MaxPorts.                                                                                                                                                                                                                                                                                                                                                                                                                      |

| 4 to 0       | Protocol Slot Type | This field specifies the Slot Type value which can specified when allocating Device Slots that support this protocol. Valid values are 0 to 31. |

**(e) Protocol Speed ID for FS Register (USB\_HOST\_PSIFS)**

Protocol speed ID for FS register.

**Access Size:** 32 bits**Address(es):** <USB\_S0\_base> + 0540h**Initial Value:** 000C\_0021h

Table 34.5-50 USB\_HOST\_PMC Register Contents (1/2)

| Bit Position | Bit Name    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 27     | PME Support | This 5-bit field indicates the power states in which the function can assert PME#. A value of 0b for any bit indicates that the function is not capable of asserting the PME# signal in that power state.<br>Bit[27] XXXX1b – PME# can be asserted from D0<br>Bit[28] XXX1Xb – PME# can be asserted from D1<br>Bit[29] XX1XXb – PME# can be asserted from D2<br>Bit[30] X1XXXb – PME# can be asserted from D3hot<br>Bit[31] 1XXXXb – PME# can be asserted from D3cold                                                                                                                     |
| 26           | D2 Support  | If this bit is 1, this function supports the D2 Power Management State.<br>Functions that do not support D2 shall always return a value of 0 for this bit.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 25           | D1 Support  | If this bit is 1, this function supports the D1 Power Management State.<br>Functions that do not support D1 shall always return a value of 0 for this bit.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 24 to 22     | Aux Current | This 3 bit field reports the 3.3 Vaux auxiliary current requirements for the PCI function.<br>If the Data Register has been implemented by this function: <ul style="list-style-type: none"> <li>Reading this field returns a value of 000b.</li> <li>The Data Register takes precedence over this field for 3.3 Vaux current requirement reporting.</li> </ul> If PME# generation from D3cold is not supported by the function (PMC (15) = 0), this field returns a value of 000b, when read.                                                                                            |
| 21           | DSI         | The Device Specific Initialization bit indicates whether special initialization of this function is required (beyond the standard PCI configuration header) before the generic class device driver is able to use it. Note that this bit is not used by some operating systems. Microsoft Windows and Windows NT, for instance, do not use this bit to determine whether to use D3. Instead, they use the driver's capabilities to determine this. A 1 indicates that the function requires a device specific initialization sequence following transition to the D0 uninitialized state. |
| 20           | —           | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 19           | PME Clock   | When this bit is 1, it indicates that the function relies on the presence of the PCI clock for PME# operation. When this bit is 0, it indicates that no PCI clock is required for the function to generate PME#.<br>Functions that do not support PME# generation in any state returns 0 for this field.                                                                                                                                                                                                                                                                                  |
| 18 to 16     | Version     | A value of 011b indicates that this function complies with revision 1.2 of the PCI Power Management Interface Specification.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| 15           | PME Status    | <p>This bit is set when the function would normally assert the PME# signal independent of the state of the PME_En bit.</p> <p>Writing 1 clears this bit and causes the function to stop asserting a PME# (if enabled). Writing 0 has no effect.</p> <p>This bit defaults to 0 if the function does not support PME# generation from D3cold.</p> <p>If the function supports PME# from D3cold, then this bit is sticky and shall be explicitly cleared by the operating system each time the operating system is initially loaded.</p>                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 14, 13       | Data Scale    | <p>This 2-bit read-only field indicates the scaling factor to be used when interpreting the value of the Data register. The value and meaning of this field will vary depending on which data value has been selected by the Data_Select field. This field is a required component of the Data register (offset 7) and shall be implemented if the Data register is implemented. If the Data register has not been implemented, this field shall return 00b when the PMCSR is read.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 12 to 9      | Data Select   | <p>This 4-bit field is used to select which data is to be reported through the Data register and Data_Scale field. This field is a required component of the Data register (offset 7) and shall be implemented if the Data register is implemented. If the Data register is not implemented, this field should be read only and return 0000b when the PMCSR is read</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 8            | PME En        | <p>Writing 1 to this bit enables the function to assert PME#.</p> <p>When 0, PME# assertion is disabled.</p> <p>This bit defaults to 0 if the function does not support PME# generation from D3cold. If the function supports PME# from D3cold, then this bit is sticky and shall be explicitly cleared by the operating system each time it is initially loaded. Functions that do not support PME# generation from any D-state (i.e., PMC (15:11) = 0_0000b), can hardwire this bit to be read-only always returning 0 when read by system software.</p>                                                                                                                                                                                                                                                                                                                                                                                                    |
| 7 to 4       | —             | Reserved. These bits are read as 0b. Writing is invalid.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 3            | No Soft Reset | <p>When set (1), this bit indicates that devices are transitioning from D3hot to D0 because of PowerState commands do not perform an internal reset. Configuration Context is preserved. Upon transition from the D3hot to the D0 Initialized state, no additional operating system intervention is required to preserve Configuration Context beyond writing the PowerState bits.</p> <p>When clear (0), devices do perform an internal reset upon transitioning from D3hot to D0 via software control of the PowerState bits. Configuration Context is lost when performing the soft reset. Upon transition from the D3hot to the D0 state, full reinitialization sequence is needed to return the device to D0 Initialized.</p> <p>Regardless of this bit, devices that transition from D3hot to D0 by a system or bus segment reset will return to the device state D0 Uninitialized with only PME context preserved if PME is supported and enabled.</p> |

| Bit Position | Bit Name               | Description                                                                                                                                                                                                                                                                                                           |
|--------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 2      | —                      | Reserved                                                                                                                                                                                                                                                                                                              |
| 1            | Interrupt Enable (IE)  | Default = 0. This flag specifies whether the Interrupter is capable of generating interrupts. When this bit and the IP bit are set to (1), the Interrupter generates an interrupt when the Interrupter Moderation Counter reaches 0. If this bit is 0, then the Interrupter is prohibited from generating interrupts. |
| 0            | Interrupt Pending (IP) | Default = 0. This flag represents the current state of the Interrupter. If IP = 1, an interrupt is pending for this Interrupter. A 0 value indicates that no interrupt is pending for the Interrupter.                                                                                                                |

(b) Interrupter Moderation Register (USB\_HOST\_IMOD)

Interrupter moderation register.

Access Size: 32 bits  
Address(es): <USB\_S0\_base> + 0624h  
Initial Value: 0000\_0FA0h

Table 34.5-54 USB\_HOST\_IMOD Register Contents

| Bit Position | Bit Name                              | Description                                                                                                                                                                                                                                                                                                                                            |
|--------------|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 16     | Interrupt Moderation Counter (IMODC)  | Default = undefined. Down counter. Loaded with the IMODI value whenever IP is cleared to 0, counts down to 0, and stops. The associated interrupt is signaled whenever this counter is 0, the Event Ring is not empty, the IE and IP flags = 1, and EHB = 0. This counter can be directly written by software at any time to alter the interrupt rate. |
| 15 to 0      | Interrupt Moderation Interval (IMODI) | Default = '4000' (up to 1 ms). Minimum inter-interrupt interval. The interval is specified in 250ns increments. A value of 0 disables interrupt throttling logic and interrupts are generated immediately if IP = 0, EHB = 0, and the Event Ring is not empty.                                                                                         |

(c) Event Ring Registers

Event Ring Segment Table Size Register (USB\_HOST\_ERSTSZ)

Event ring segment table size register.

Table 34.5-55 USB\_HOST\_ERSTSZ Register Contents

| Bit Position | Bit Name                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 16     | —                             | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 15 to 0      | Event Ring Segment Table Size | Default = 0. This field identifies the number of valid Event Ring Segment Table entries in the Event Ring Segment Table pointed to by the Event Ring Segment Table Base Address register. The maximum value supported by an xHC implementation for this register is defined by the ERST Max field in the HCSPARAMS2 register. For the Primary Interrupter: Writing a value of 0 to this field results in undefined behavior of the Event Ring. The Primary Event Ring cannot be disabled. |

Event Ring Segment Table Base Address Low Register (USB\_HOST\_ERSTBAL)

Event ring segment table base address low register.

Access Size: 32 bits  
Address(es): <USB\_S0\_base> + 0630h  
Initial Value: 0000\_0000h

Table 34.5-56 USB\_HOST\_ERSTBAL Register Contents

| Bit Position | Bit Name                                           | Description                                                                                                                                                                                                                                                                       |
|--------------|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 6      | Event Ring Segment Table Base Address Low Register | Default = 0. This field defines the lower-order bits of the address of where the Event Ring Segment Table starts.<br>Writing to this register sets advancement of the event ring state machine (EREP) to the start state. This field shall not be modified if HCHalted (HCH) = 0. |
| 5 to 0       | —                                                  | Reserved                                                                                                                                                                                                                                                                          |

Event Ring Segment Table Base Address High Register (USB\_HOST\_ERSTBAH)

Event ring segment table base address high register.

Access Size: 32 bits  
Address(es): <USB\_S0\_base> + 0634h  
Initial Value: 0000\_0000h

Table 34.5-57 USB\_HOST\_ERSTBAH Register Contents

| Bit Position | Bit Name                                            | Description                                                                                                                                                                                                                                                                        |
|--------------|-----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | Event Ring Segment Table Base Address High Register | Default = 0. This field defines the higher-order bits of the start address where the Event Ring Segment Table starts. Writing to this register sets advancement of the event ring state machine (EREP) to the start state. This field shall not be modified if HCHalted (HCH) = 0. |

Event Ring Dequeue Pointer Low Register (USB\_HOST\_ERDPL)

Event ring dequeue pointer low register.

Access Size: 32 bits  
Address(es): <USB\_S0\_base> + 0638h  
Initial Value: 0000\_0000h

Table 34.5-58 USB\_HOST\_ERDPL Register Contents

| Bit Position | Bit Name                          | Description                                                                                                                                                                                                                                                                 |
|--------------|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 4      | Event Ring Dequeue Pointer Low    | Default = 0. This field defines the lower-order bits of the 64-bit address of the current Event Ring Dequeue Pointer.                                                                                                                                                       |
| 3            | Event Handler Busy (EHB)          | Default = 0. This flag is set to 1 when the IP bit is set to 1 and cleared to 0 by software when the Dequeue Pointer register is written.                                                                                                                                   |
| 2 to 0       | Dequeue ERST Segment Index (DESI) | Default = 0. This field can be used by the xHC to accelerate checking the Event Ring full condition. This field is written with the lower-order 3 bits of the offset of the ERST entry which defines the Event Ring segment that the Event Ring Dequeue Pointer resides in. |

Event Ring Dequeue Pointer High Register (USB\_HOST\_ERDPH)

Event ring dequeue pointer high register.

Access Size: 32 bits  
Address(es): <USB\_S0\_base> + 063Ch  
Initial Value: 0000\_0000h

Table 34.5-59 USB\_HOST\_ERDPH Register Contents

| Bit Position | Bit Name                        | Description                                                                                                            |
|--------------|---------------------------------|------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | Event Ring Dequeue Pointer High | Default = 0. This field defines the higher-order bits of the 64-bit address of the current Event Ring Dequeue Pointer. |

34.5.4.6 Doorbell Registers

(1) Host Controller Doorbell Register (USB\_HOST\_HCD)

Host controller doorbell register.

Access Size: 32 bits  
Address(es): <USB\_S0\_base> + 0700h  
Initial Value: 0000\_0000h

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

**Initial Value:** 0000\_0000h

Table 34.5-61 USB\_HOST\_DCDm Register Contents

| Bit Position | Bit Name     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 16     | DB Stream ID | Doorbell Stream ID. If the endpoint of a Device Context Doorbell defines streams, then this field can be used to identify the stream of the endpoint the doorbell reference is targeting. System software is responsible for ensuring that the value written to this field is valid. If the endpoint defines streams (MaxPStreams > 0), then 0, 65535 (no stream) and 65534 (prime) are reserved stream ID values and shall not be written to this field. If the endpoint does not define streams (MaxPStreams = 0) and a non-0 value is written to this field, the doorbell reference shall be ignored. This field only applies to Device Context Doorbells and shall be cleared to '0' for Host Controller Command Doorbells. This field returns '0' when read.                                                                                                                         |
| 15 to 8      | —            | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| 14                                        | No Frame Length Timing Capability (NFC)           | This flag indicates whether the host controller implementation supports a Frame Length Timing Value. A 1b in this bit indicates that the Frame Length Timing Value is not supported. A 0b in this bit indicates that the Frame Length Timing Value is supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                           |                      |       |        |       |        |       |        |     |  |       |         |       |         |     |  |       |         |       |         |
| 13 to 8                                   | Frame Length Adjustment (FLADJ)                   | <div>Each decimal value change to this register corresponds to 16 high-speed bit times. The SOF cycle time (number of SOF counter clock periods to generate an SOF microframe length) is equal to 59488 + value in this field. The default value is decimal 32 (20h), which gives an SOF cycle time of 60000.</div> <div>Table 34.5-80-1</div> <table><tr><th>Frame Length<br/>(# HS bit times)(decimal)</th><th>FLADJ Value(decimal)</th></tr><tr><td>59488</td><td>0(00h)</td></tr><tr><td>59504</td><td>1(01h)</td></tr><tr><td>59520</td><td>2(02h)</td></tr><tr><td>...</td><td></td></tr><tr><td>59984</td><td>31(1Fh)</td></tr><tr><td>60000</td><td>32(20h)</td></tr><tr><td>...</td><td></td></tr><tr><td>60480</td><td>62(3Eh)</td></tr><tr><td>60496</td><td>63(3Fh)</td></tr></table> | Frame Length<br>(# HS bit times)(decimal) | FLADJ Value(decimal) | 59488 | 0(00h) | 59504 | 1(01h) | 59520 | 2(02h) | ... |  | 59984 | 31(1Fh) | 60000 | 32(20h) | ... |  | 60480 | 62(3Eh) | 60496 | 63(3Fh) |

**(2) Battery Charging Register****(a) Battery Charging Control Register (USB\_HOST\_BCCTRL)**

Battery charging control register.

**Access Size:** 32 bits

**Address(es):** <USB\_S0\_base> + 1080h

**Initial Value:** 0000\_0000h

34.5.5 Description of Functions

The prefix (USB\_HOST\_) of the register names is omitted in this and subsequent sections.

34.5.5.1 Battery Charging

The USB3HOST supports the Battery Charging function of the Charging Port Device which is on the supply side.

The Battery Charging function is used to pull more current from VBUS than the current specified in the USB specification.

The following Port Modes are supported in the USB3HOST;

- Standard Downstream Port (SDP)
- Charging Downstream Port (CDP)
- Dedicated Charging Port (DCP)

NOTE

For detail, please refer to the Battery Charging Specification Revision1.2.

(1) Setting Battery Charging Mode

The user can select one of BC modes by setting BCCTRL.BC\_MODE\_P[m] (m : 1)’s field in Battery Charging Control Register (BCCTRL) [Refer to **Section 34.5.4.7(2)(a)**], when the user uses the battery charging function.

Table 34.5-82 BC\_MODE\_P[m]’s information of Battery Charging Control Register (BCCTRL)

| Bit | Field      | SW | Default Value | Function                                                                     |
|-----|------------|----|---------------|------------------------------------------------------------------------------|
| 1:0 | BC_MODE_P1 | RW | 0h            | Battery Charging Mode for Port1<br>0: SDP<br>1: CDP<br>2: DCP<br>3: Reserved |

## (2) How to Set Battery Charging Mode

The host driver can set the battery charging mode by executing the flow in the **Figure 34.5-2**.

Figure 34.5-2 Host Driver's Flow to Set BC Mode (m = 1)

### 34.5.5.2 Initialization Flow

**Figure 34.5-3** shows the “initialization flow” to the USB3HOST in USB system.

Figure 34.5-3 Initialization Flowchart

1. Set Core Defined Register

Information of related interrupts is set in this phase.

### 34.5.5.3 xHCD Initialization Flow

Figure 34.5-4 shows the “initialization flow by xHCD (xHCI Driver)” to the USB3HOST in USB system.

Figure 34.5-4 Initialization Flowchart by xHCD (xHCI Driver)

1. Initialize Memory Map  
xHCD initializes the memory area in the system.
2. Reset xHC  
xHCD confirms that USBSTS.HCH is set to “1b”.  
Then, xHCD resets xHC (the USB3HOST) by setting USBCMD.HCRST to “1b”.
3. Wait for setting HCRST to “0”  
xHCD waits for setting USBCMD.HCRST to “0b”.
4. Wait for xHC's Ready  
xHCD waits for setting USBSTS.CNR to “0b”.

5. Set CONFIG  
xHCD sets CONFIG.MaxSlotsEn to a valid value.
6. Set DCBAAP  
xHCD sets the “Device Context Base Address Array (DCBAAP)” to a valid value.
7. Set CRCR  
xHCD sets the “Command Ring Control Register (CRCR)” to the Command Ring’s address.
8. Set ERST  
xHCD sets the “Event Ring Segment Table (ERST)” to the Event Ring’s address and size in the system memory.
9. Set ERSTSZ  
xHCD sets the “Event Ring Segment Table Size (ERSTSZ)” to the Event Ring Segment Table’s size.
10. Set ERDP  
xHCD sets the “Event Ring Dequeue Pointer (ERDP) Register” to the Event Ring’s read address.
11. Set ERSTBA  
xHCD sets the “Event Ring Segment Table Base Address (ERSTBA) Register” to the Event Ring Segment Table’s address.
12. Set USBCMD  
xHCD sets USBCMD.INTE to “1b” and also sets USBCMD.R/S to “1b”.

### 34.5.5.4 Interrupt Flow

#### (1) “all\_int” Interrupt Flow

Figure 34.5-5 shows “all\_int” interrupt flow in USB system.

Figure 34.5-5 “all\_int” Interrupt Flowchart

## (2) XHC Interrupt Flow

**Figure 34.5-6** shows “xhc\_int” interrupt flow in USB system.

In the case of “CFGSTS1.INTEDGEN = 0”, the notification mode of “xhc\_int” is the Level mode.

(This mode is the same as INTA# in PCI System.)

In the case of “CFGSTS1.INTEDGEN = 1”, the notification mode of “xhc\_int” is the Pulse mode.

(This is the same as MSI / MSI-X in PCI System.)

In this LSI, “level mode” is selected as default interrupt mode.

Figure 34.5-6 XHC Interrupt Flowchart

(3) PME Interrupt Flow

Figure 34.5-7 shows “pme\_int”’s interrupt flow in USB system.

Figure 34.5-7 PME Interrupt Flowchart

#### (4) HSE Interrupt Flow

Figure 34.5-8 shows “hse\_int”'s interrupt flow in USB system.

Figure 34.5-8 HSE Interrupt Flowchart

**(5) SMI Interrupt Flow**

**Figure 34.5-9** shows “smi\_int”'s interrupt flow in USB system.

Figure 34.5-9 SMI Interrupt Flowchart

1. Write interrupt's factor's register-bit = 1
  - If this interrupt's factor is USBLEGCTLSTS.SBA, write "1" to USBLEGCTLSTS.SBA.
  - If this interrupt's factor is USBLEGCTLSTS.SPC, write "1" to USBLEGCTLSTS.SPC.
  - If this interrupt's factor is USBLEGCTLSTS.SOOC, write "1" to USBLEGCTLSTS.SOOC.
  - If this interrupt's factor is USBLEGCTLSTS.SHSE, write "1" to USBSTS.HSE.
  - If this interrupt's factor is USBLEGCTLSTS.SEI, write "1" to USBSTS.EINT.

### 34.5.5.5 xHCI Command

**Figure 34.5-10** shows an abstract of xHCI Command flow by using the USB3HOST.

Refer to section 4.11.3 “Event TRBs” and section 4.11.4 “Command TRBs” of the xHCI specification for detail information.

Figure 34.5-10 xHCI Command Flowchart

1. Set Command TRB  
Host driver sets the Command TRB in the Command Ring.
2. Doorbell Ring  
Host driver rings the Doorbell to prepare data for each xHCI command's process.
3. Command TRB Fetch  
The USB3HOST fetches Command TRB from Command Ring,
4. Each command process  
The USB3HOST decodes that command's content and executes each command process.
5. Transfer Event TRB  
The USB3HOST writes Event TRB to Event Ring.
6. xHC Interrupt  
The USB3HOST sends the interrupt to the system.

### 34.5.5.6 Examples of Transactions' Flow

This section describes transactions when the USB3HOST is used.

As examples, Bulk OUT and Bulk IN transactions are described.

The USB3HOST complies with the xHCI Specification.

Refer to section 4.11.2 “Transfer TRBs” and section 4.11.3 “Event TRBs” of the xHCI Specification for detail information.

#### Bulk OUT Transaction Flow

Bulk OUT transaction flow is shown below.

Figure 34.5-11 Example of Bulk OUT Transaction Flowchart

1. Doorbell Ring  
Host Driver rings Doorbell to prepare Transfer Data.
2. TRB Fetch  
The USB3HOST fetches TRB from OUT Transfer Ring,
3. Read OUT Data  
The USB3HOST reads OUT Data from Data Buffer Pointer.
4. Transfer Event  
The USB3HOST writes Transfer Event TRB to Event Ring.
5. xHC Interrupt  
The USB3HOST sends the interrupt to the system.

### Bulk IN transaction

Bulk IN transaction flow is shown below.

Figure 34.5-12 Example of Bulk IN Transaction Flowchart

1. Doorbell Ring  
Host driver rings Doorbell to prepare Transfer Data.
2. TRB Fetch  
The USB3HOST fetches TRB from OUT Transfer Ring,
3. Write IN Data  
The USB3HOST writes IN Data to Data Buffer Pointer.
4. Transfer Event  
The USB3HOST writes Transfer Event TRB to Event Ring.
5. xHC Interrupt  
The USB3HOST sends the interrupt to the system.

#### **34.5.5.7 Functional Implementation Constraint**

The USB3HOST core has functional implementation constraints.

**One packet shall be composed of 8TRBs or less.**

If one packet is composed of nine or more TRBs, the USB3HOST generates a TRB Error for the higher-level system.

**SW shall not set to U3 state before an event of the Force Header Command is completed.**

If SW sets to U3 state before this event is completed, the USB3HOST results in undefined xHC behavior.

## 34.6 USB3.1 Gen1 Peripheral Controller (USB3PERI)

### 34.6.1 Introduction

USB3.1 Gen1 Peripheral Controller (USB3PERI) is compliant with USB3.1 specification and enables connectivity to USB3.1 system with proven design experiences. It works as USB3.1 device when connected to USB host controller supporting USB3.1, and it works as USB2.0 device when connected to USB host controller supporting not USB3.1 but USB2.0. USB3PERI is compliant with USB2.0 specification as well when it works as USB2.0 device.

USB3PERI contains two function blocks, EPC (endpoint controller) function and AXI-bridge function (as both of master and slave).

#### 34.6.1.1 Features

The features of USB3PERI are as follows.

- *Universal Serial Bus 3.1 Specification Revision 1.0 and ECNs approved in June 27, 2017*
- *Universal Serial Bus Specification Revision 2.0 April 27, 2000*
- *USB 2.0 Link Power Management Addendum Engineering Change Notice to the USB 2.0 specification as of July 16, 2007*

#### (1) USB3.1 Function

- USB3.1 Gen1 super-speed (5 Gbps) transfer
- Stream ID control supported (UASP can be supported)
- Suspend/Resume function
  - Power Management by sending/receiving of link commands (PHY clock stop is supported) is supported.
  - Remote Wakeup request can be transmitted.

#### (2) USB2.0 Function

- USB2.0 high-speed (480 Mbps) and USB2.0 full-speed (12 Mbps) transfer
- Suspend/Resume function
  - Power Management provided by Suspend/Resume (PHY clock stop is supported) is supported.
  - Remote Wakeup request can be transmitted.
  - Link Power Management (LPM) is supported.

### 34.6.1.2 Block Diagram

Block components in USB3PERI are shown in **Figure 34.6-1**.

Figure 34.6-1 USB3PERI Block Diagram

34.6.2 Register Map

For the register base address (<USB\_S1\_base>), see the section of Address Map.

34.6.2.1 USB3PERI Address Space

There are 4 register groups, AXI-IF registers, EPC registers, SSIF registers and PHY registers inside USB3PERI.

PHY registers are mapped to the same address space as EPC registers and SSIF registers, but it can be accessed when AXI\_CON.PHY\_CTRL = 1.

Figure 34.6-2 Register Address Map

### 34.6.2.2 AXI Register

AXI register groups are selectable from 4 groups or 14 groups, which have information of PRD Table. This unit only supports AXI Register Mode 2 (14 register groups).

#### (1) AXI Register Mode 2 (14 register groups to have the information of PRD Table)

Table 34.6-1 AXI Register Mode 2 (14 register groups to have the information of PRD Table) List (1/3)

|                                                      |                  |                  |                 |                 |                 |                  |                 |                |
