### 34.6.3 Register Descriptions

The function description of each register is given below.

The prefix (USB\_PERI\_) of the register names is omitted in the register descriptions and the field descriptions in this section.

#### 34.6.3.1 AXI Register

##### (1) AXI Register Mode 2 (14 register groups to have the information of PRD Table)

###### (a) AXI Control Register (AXI\_CON)

This register is used to control the basic functions of AXI-IF.

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + 0000h

**Initial Value:** 2003\_2200h

| Bit           | 31        | 30              | 29              | 28              | 27 | 26               | 25 | 24       | 23              | 22 | 21 | 20 | 19 | 18 | 17              | 16        |

**(d) AXI Interrupt Enable Register (AXI\_INT\_ENA)**

This register is used to enable interrupts from AXI-IF.

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + 000Ch

**Initial Value:** 0000\_0000h

| Bit           | 31         | 30         | 29              | 28              | 27              | 26              | 25              | 24             | 23             | 22             | 21             | 20             | 19             | 18             | 17             | 16             |

**(e) DMA Interrupt Status Register (DMA\_INT\_STA)**

This register shows the interrupt statuses of DMA transfers with each PIPE.

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + 0010h

**Initial Value:** 0000\_0000h

Table 34.6-8 DMA\_INT\_STA Register Contents (2/2)

| Bit Position | Bit Name      | Description                                                                                                               |
|--------------|---------------|---------------------------------------------------------------------------------------------------------------------------|
| 6            | P6_DMACNG_STA | This bit indicates that the status of DMA transfer with PIPE6 is changed.<br>This bit is cleared when 1 is written to it. |
| 5            | P5_DMACNG_STA | This bit indicates that the status of DMA transfer with PIPE5 is changed.<br>This bit is cleared when 1 is written to it. |
| 4            | P4_DMACNG_STA | This bit indicates that the status of DMA transfer with PIPE4 is changed.<br>This bit is cleared when 1 is written to it. |
| 3            | P3_DMACNG_STA | This bit indicates that the status of DMA transfer with PIPE3 is changed.<br>This bit is cleared when 1 is written to it. |
| 2            | P2_DMACNG_STA | This bit indicates that the status of DMA transfer with PIPE2 is changed.<br>This bit is cleared when 1 is written to it. |
| 1            | P1_DMACNG_STA | This bit indicates that the status of DMA transfer with PIPE1 is changed.<br>This bit is cleared when 1 is written to it. |
| 0            | Reserved      | This bit is read only. The value of this bit is 0.                                                                        |

**(f) DMA Interrupt Enable Register (DMA\_INT\_ENA)**

This register is used to enable interrupts of DMA Transfers with each PIPEs.

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + 0014h

**Initial Value:** 7FFF\_FFEh

| 5            | PRD_EN6_R    | This bit indicates the status of PRD_EN6.<br>This bit shows the same value as that of bit0 (PRD_EN6) in DMA_CH0_CON6 register, but it is used as read-only bit.    |
| 4            | PRD_EN5_R    | This bit indicates the status of PRD_EN5.<br>This bit shows the same value as that of bit0 (PRD_EN5) in DMA_CH0_CON5 register, but it is used as read-only bit.    |
| 3            | PRD_EN4_R    | This bit indicates the status of PRD_EN4.<br>This bit shows the same value as that of bit0 (PRD_EN4) in DMA_CH0_CON4 register, but is used as read-only bit.       |
| 2            | PRD_EN3_R    | This bit indicates the status of PRD_EN3.<br>This bit shows the same value as that of bit0 (PRD_EN3) in DMA_CH0_CON3 register, but is used as read-only bit.       |
| 1            | PRD_EN2_R    | This bit indicates the status of PRD_EN2.<br>This bit shows the same value as that of bit0 (PRD_EN2) in DMA_CH0_CON2 register, but it is used as read-only bit.    |

Table 34.6-11 AXI\_EXT\_STA Register Contents (3/3)

| Bit Position | Bit Name  | Description                                                                                                                                                     |
|--------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | PRD_EN1_R | This bit indicates the status of PRD_EN1.<br>This bit shows the same value as that of bit0 (PRD_EN1) in DMA_CH0_CON1 register, but it is used as read-only bit. |

**(i) DMA Ch0 Control Register n (DMA\_Ch0\_CONn)**

This register is used to control DMA transfer with PRD table.

When it is required to change the setting in this register, disable PRD\_ENn (=0) and make sure that DMA transfer on DMA\_Ch0\_CONn is not being executed before the change.

n = 1 to 14

ADDCh: 020 + (010 × n)

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + ADDCh

**Initial Value:** 0000\_0000h

(j) DMA Ch0 PRD Address Register n (DMA\_Ch0\_PRD\_ADRn)

This register is used to control DMA transfer with PRD table.

When it is required to change the setting in this register, disable DMA\_Ch0\_CONn.PRD\_ENn(=0) and make sure that DMA transfer on DMA\_Ch0\_CONn is not being executed before the change.

n = 1 to 14

ADDP: 024 + (010 × n)

Access Size: 32 bits  
Address(es): <USB\_S1\_base> + ADDPh  
Initial Value: 0000\_0000h

| 31 to 0      | PRD_ADRn[31:0] | This field specifies the address of PRD table used for DMA transfer on DMA_Ch0_CONn. If the transfer on DMA_Ch0_CONn has been started, this field may show the address of PRD table being used at present. The value of this field after the transfer is completed is undefined. |

### 34.6.3.2 Physical Region Descriptor (PRD) Table

Physical Region Descriptor (PRD) table is used to give the source or destination address, the size and other settings for the transfer to AXI-IF. It is assumed that the software prepares PRD table in system memory and assign it to DMA\_Ch0\_CONx.

PRD table is prepared individually for each PIPE and PIPEs cannot share a PRD table.

Make sure that PRD table does not cross the 4KB address boundary in system memory.

The format of PRD table and the definitions of fields are as follows.

Figure 34.6-3 PRD Table Format

Table 34.6-14 1st Word in PRD Table (1/3)

| Bit | Field Name | Updated by | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Bit     | Field Name | Updated by | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------|------------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15 to 0 | SIZE       | FW<br>HW   | <p>This field specifies the number of byte to be transferred.</p> <p>This field is updated to “the number of remaining bytes to be transferred” by hardware at each end of transfer of packet.</p> <p>The value from 1 byte to 64 Kbytes can be specified in this register.</p> <p>The meaning of 0000h differs depending on the statuses of Lst bit and ZL bit. If Lst = 1 and ZL = 1, 0000h means 0 byte. Otherwise, 0000h means 64 Kbytes. If it is required that data of 64 Kbytes is sent then ZLP is sent in order to show the boundary of transfer, prepare two PRD tables. The first PRD table has data of 64 Kbytes with Lst = 0, ZL = 0 and SIZE = 0000h (64 Kbytes), and the second PRD table has data of 0byte with Lst=1, ZL=1 and SIZE = 0000h (0 bytes).</p> <p>It is not allowed to divide a single USB packet into two or more PRD tables.</p> <p>For OUT direction, the transfer following the PRD table is terminated when USB3PERI receives the short packet. The initial value in this field should be multiples of the max packet size so that the last packet is accepted even when its size is the max packet size.</p> <p>For IN direction, if the size of data to be transferred is not multiples of the max packet size, the residue is transmitted as the last packet.</p> <p>In case of link pointer, set 0 to this field.</p> |

| 31 to 0 | BAP        | FW<br>HW   | <p>In case that Type bit is buffer pointer:</p> <p>This field indicates the start address of data.</p> <p>In this case, the next descriptor should be placed continuously in system memory.</p> <p>In case that Type bit is link pointer:</p> <p>This field indicates the address of next descriptor.</p> <p>In this case, the lower 3 bits of the address of descriptor should be 0.</p> <p>This field is updated at each end of transfer of packet.</p> <p>The value in this field is undefined when the transfer is terminated by receiving short packet or when the transfer is terminated due to error.</p> |

### 34.6.3.3 EPC Register

#### (1) USB Common Control Register (USB\_PERI\_USB\_COM\_CON)

This register provides the common functions to control USB3.1/USB2.0 behavior.

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + 0200h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30                             | 29 | 28 | 27 | 26 | 25 | 24   | 23                | 22                | 21              | 20 | 19 | 18 | 17                                                      | 16                              |

These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 1            | USB3.1 RX Detection (RX_DETECTION) | This bit is used to start USB3.1 Rx Detection. When 1 is written to this bit, USB3PERI starts USB3.1 Rx Detection.<br>This bit is valid only when USB30_CON.B3_CONNECT = 1 and PORTSC.PLS[3:0] is in Disabled state.<br>This bit is write only and the value read from this bit is always 0.                                                                                                                                                                                                                                  |
| 0            | PIPE Clear (PIPE_CLR)              | This bit is used to initialize all PIPEs (PIPE0-PIPEn). When 1 is written to this bit, sequence numbers, data PIDs and data buffers are initialized.<br>It has the same meaning to set all P0_CON.P0_CLR and Pn_CON.Pn_CLR for all PIPEs.<br>The time required to initialize PIPEs varies depending on the number of PIPEs. When this bit shows 1, it means that the initialization of all PIPEs is still being executed.<br>It is prohibited to access other registers until this bit becomes 0 after writing 1 to this bit. |

**(2) USB20 Control Register (USB\_PERI\_USB20\_CON)**

This register provides the basic functions to control USB2.0(HS/FS) behavior.

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + 0204h

**Initial Value:** 0000\_0000h

| 0            | USB2 Testmode<br>Enable<br>(B2_TSTMOD_EN) | When this bit is set to 1, the selected test function in USB20_CON.B2_TSTMODE[2:0] is enabled.<br>This bit is write only and the value read from this bit is always 0.                                                                                                                                                                                                                                                                                                                                                                        |

**(3) USB30 Control Register (USB\_PERI\_USB30\_CON)**

This register provides the basic functions to control USB3.1 (SS) behavior.

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + 0208h

**Initial Value:** 1000\_0000h

| 26 to 24     | Power State Change Select (POW_SEL[2:0]) | <p>This field is used to request to change POWERDOWN mode (PHY_POWERDOWN[1:0]).</p> <p>000b: Transition from P0 to P2 in disconnected state (SS.Disabled)</p> <p>001b: Transition from P0 to P3 in disconnected state (SS.Disabled)</p> <p>010b: Transition from P2 to P0 in disconnected state (SS.Disabled)</p> <p>011b: Reserved</p> <p>100b: Transition from P0 to P2 in U3 state</p> <p>101b: Transition from P0 to P3 in U3 state</p> <p>110b: Transition from P2 to P0 in U3 state</p> <p>111b: Reserved</p> <p>Transition of POWERDOWN mode other than above is automatically operated by USB3PERI.</p> <p><i>Note:</i> That it is also required to set USB30_CON.POW_SEL_WEN when this field is used. If not, the request in this field is ignored. It is notified on USB_INT_STA_1.B3_PSSUCS_STA or USB_INT_STA_1.B3_PSFAIL_STA whether the transition succeeded or failed.</p> <p><i>Note:</i> This field cannot be used to request the transition from P3. In that case, the transition is automatically operated by hardware. This register cannot be accessed when clock from USB3.1-PHY is suspended. Make sure to confirm clock from USB3.1 PHY is running when accessing to this register.</p> |
| 23           | USB30-PHY PLL WAKEUP (B3_PLLWAKE)        | <p>This bit is used to change POWERDOWN mode from P3 to P0 in order to wake up PLL in case PHY_POWERDOWN[1:0] is in P3 state (PLL is stopped).</p> <p>Transition from P3 to P0 wakes up PLL.</p> <p>This bit is not cleared automatically after PLL is woken up. So make sure to clear this bit by software after confirming PLL is running.</p> <p>1b: Requesting to wake up PLL</p> <p>0b: Normal state</p> <p>The registers related to USB3.1 function cannot respond to the access when clock from USB3.1 PHY is stopped, and it can cause hung-up. Make sure to confirm clock from USB3.1 PHY is running when accessing the registers related to USB3.1 function</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 22 to 20     | —                                        | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 19, 18       | LPS Enable (LPS_ENABLE[1:0])             | <p>This field specifies the response to LGO_U1/LGO_U2.</p> <p>00b: Accept (default)</p> <p>USB3PERI basically accepts LPM request (But it might be rejected due to other reasons. Especially the hardware will reject when it has data to be transmitted).</p> <p>01b: Forced Accept</p> <p>USB3PERI always accepts LGO_Ux request and sends LAU as the response. It also sends LGO_Ux to request the transition to low power state when PORTPMSC.Ux_TIMEOUT[7:0] is expired.</p> <p>10b: Forced Reject</p> <p>USB3PERI always rejects LGO_Ux request and sends LXU as the response. It never sends LGO_Ux even when PORTPMSC.Ux_TIMEOUT[7:0] is expired.</p> <p>11b: Reserved</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 17           | USB3 Vbus CONNECT (B3_CONNECT)           | <p>This bit is used for USB3.1 connection. Set this bit to 1 to start USB3.1 connection.</p> <p>The value in this bit is output on the signal "B3_CONNECT" directly.</p> <p>Note that it might be required to wait approx. 100 ms to change the value in this bit after detecting VBUS is changed in order to remove the influence of chattering of VBUS. See <b>Section 34.6.5.3(2), USB Connection</b> for details.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 16           | USB3 PHY Reset (B3_PHYRST)               | <p>This bit is used to reset USB3.1 PHY.</p> <p>The value in this bit is output on the signal "B3_PHY_RESET" directly.</p> <p>USB3PERI also outputs "1" on B3_PHY_RESET when ARESETn is asserted.</p> <p>1b: Reset</p> <p>0b: No reset</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 15 to 3      | —                                        | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Bit Position | Bit Name                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2            | POW_SEL Write Enable (POW_SEL_WEN)      | When this bit is set to 1, the transition selected in USB30_CON.POW_SEL[2:0] is requested.<br>This bit is write only and the value read from this bit is always 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 1            | USB3 Hot Reset Complete (B3_HOTRST_CMP) | This bit is used to notify the link layer of USB3PERI that the software process of hot reset has been completed and it can complete the reset sequence.<br>Set this bit to 1 when the Hot Reset Process operation is complete.<br>The reception of TS1/TS2 in which hot reset bit is set is notified on USB_INT_STA_1.B3_HOTRST_STA. Since the timeout of hot reset is defined as 12 ms in USB3.1 specification, make sure that the operation for hot reset has been completed and set this bit to 1 within 12 ms from the time USB_INT_STA_1.B3_HOTRST_STA is asserted.<br>After this bit is set to 1, USB3PERI sends TS1 or TS2 in which hot reset bit is cleared to show that hot reset has been completed.<br>This bit is write only and the value read from this bit is always 0. |
| 0            | USB3 TP Send (B3_TP_SEND)               | This bit is used to allow the transmission of TP Data which is written to USB3_TPDAT0/1/2 register. When this bit is set to 1, USB3PERI sends TP_DATA which is written to USB3_TPDAT0/1/2 register.<br>When warm reset or hot reset is detected before the transmission of TP Data, the transmission is cancelled.<br>This bit is write only and the value read from this bit is always 0.                                                                                                                                                                                                                                                                                                                                                                                             |

**(4) USB Status Register (USB\_PERI\_USB\_STA)**

This register shows the status of several features of USB.

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + 0210h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22                | 21 | 20 | 19 | 18 | 17 | 16 |

| Bit Position | Bit Name | Description                                                               |
|--------------|----------|---------------------------------------------------------------------------|
| 31 to 11     | —        | Reserved. These bits are read as 0b.                                      |
| 10 to 0      | B2_FRAME | This field shows the frame number received in (u)SOF in USB2.0 operation. |

**(6) USB Interrupt Status 1 Register (USB\_PERI\_USB\_INT\_STA\_1)**

This register indicates the interrupt statuses related to USB functions.

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + 0220h

**Initial Value:** 0000\_0000h

| Bit           | 31                     | 30                     | 29                     | 28                    | 27                     | 26                    | 25                     | 24                    | 23 | 22                    | 21                    | 20                    | 19                    | 18                    | 17                    | 16                    |

Table 34.6-21 USB\_PERI\_USB\_INT\_STA\_1 Register Contents (1/3)

| Bit Position | Bit Name                                                    | Description                                                                                                                                                                                                      |
|--------------|-------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31           | PLL Wakeup Status<br>(B3_PLLWKUP_STA)                       | This bit is set to 1 when PHY30_CLK125_IN has been resumed due to PLL wakeup (USB30_CON.B3_PLLWAKE is set or the input signal "B3_PLL_WAKEIN" is asserted) or U3 Wakeup LFPS from host.                          |
| 30           | USB3 LinkUp Success Status<br>(B3_LUPSUCS_STA)              | This bit is set to 1 when the link of USB3.1 has been established (LTSSM enters U0 state from Polling state).                                                                                                    |
| 29           | Enter USB3 Polling Status<br>(B3_POLLING_STA)               | This bit is set to 1 when LTSSM has entered Polling state.                                                                                                                                                       |
| 28           | Enter USB3 Inactive Status<br>(B3_INACTV_STA)               | This bit is set to 1 when LTSSM has entered Inactive state.                                                                                                                                                      |
| 27           | Enter USB3 Disabled Status<br>(B3_DISABLE_STA)              | This bit is set to 1 when LTSSM has entered Disabled state (But this bit is set only in the case LTSSM transits to Disabled state after USB30_CON.B3_CONNECT is set to 1).                                       |
| 26           | USB3 Vendor DTEST LMP Receive Status<br>(B3_VNDTST_STA)     | This bit is set to 1 when Vendor Device Test LMP has been received.                                                                                                                                              |
| 25           | USB3 U2Inact Timeout LMP Receive Status<br>(B3_U2INACT_STA) | This bit is set to 1 when U2 Inactivity Timeout LMP has been received.<br>When U2 Inactivity Timeout LMP is received, PORTPMSC.U2_TIMEOUT is automatically updated by hardware to the value in the received LMP. |
| 24           | USB3 SetLnkFunction LMP Receive Status<br>(B3_SETLNK_STA)   | This bit is set to 1 when Set Link Function LMP has been received.<br>When Set Link Function LMP is received, PORTPMSC.FLA is automatically updated by hardware to the value in the received LMP.                |
| 23           | —                                                           | Reserved. This bit is read as 0b.                                                                                                                                                                                |

Table 34.6-21 USB\_PERI\_USB\_INT\_STA\_1 Register Contents (2/3)

| Bit Position | Bit Name                                              | Description                                                                                                                                                                                                                                                                                                  |
|--------------|-------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 22           | USB3 Link Status Change Status (B3_LNKCNG_STA)        | This bit is set to 1 when LTSSM has made the transition as listed below.<br>U0 -> U1<br>U0 -> U2<br>U0 -> U3<br>U3 -> Recovery -> U0<br>U2 -> Recovery -> U0<br>U1 -> Recovery -> U0<br>Refer to PORTSC.PLS[3:0] to know the current state.                                                                  |
| 21           | USB3 Warm Reset Receive Status (B3_WMRST_STA)         | This bit is set to 1 when warm reset has been detected.                                                                                                                                                                                                                                                      |
| 20           | USB3 Hot Reset Receive Status (B3_HOTRST_STA)         | This bit is set to 1 when hot reset has been detected.                                                                                                                                                                                                                                                       |
| 19           | USB3 Power Select Fail Status (B3_PSFAL_STA)          | This bit is set to 1 when the transition of POWERDOWN mode on USB30_CON.POW_SEL[2:0] has failed.                                                                                                                                                                                                             |
| 18           | USB3 Power Select Success Status (B3_PSSUCS_STA)      | This bit is set to 1 when the transition of POWERDOWN mode on USB30_CON.POW_SEL[2:0] has been completed successfully.                                                                                                                                                                                        |
| 17           | USB3 Enter U12 Request Receive Status (B3_U12REQ_STA) | This bit is set to 1 when USB3PERI has received LGO_U1 or LGO_U2 or when U1 TIMEOUT of U2 TIMEOUT has occurred.<br>USB3PERI responds with LAU or LXU when it receives LGO_U1 or LGO_U2, and sends LGO_U1 or LGO_U2 when U1 TIMEOUT or U2_TIMEOUT occurs, following the setting in USB30_CON.LPS_ENABLE[1:0]. |
| 16           | USB3 TP Success Status (B3_TP_SUCS_STA)               | This bit is set to 1 when the transmission of TP (Device Notification) requested on USB30_CON.B3_TP_SEND has been successfully completed.                                                                                                                                                                    |
| 15, 14       | —                                                     | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                         |
| 13           | USB2 LPM Receive Status (B2_LPMRCV_STA)               | This bit is set to 1 when USB3PERI has received LPM request from USB2.0 host and has returned ACK to it.<br>Note this bit does not mean the device has made the transition to L1. In order to confirm the device has entered L1, wait for the assertion of B2_L1SPND_STA.                                    |
| 12           | USB2 USB Reset Receive Status (B2_USBRST_STA)         | This bit is set to 1 when USB2.0 bus reset has been detected.                                                                                                                                                                                                                                                |
| 11           | USB2 L1 SPND_OUT Receive Status (B2_L1SPND_STA)       | This bit is set to 1 when the transition request to L1 has been received from USB2.0 host and the device has accepted it. USB_STA.B2_L1_SPND_OUT is changed from 0 to 1 in that case.                                                                                                                        |
| 10           | USB2_L1 RSUM_OUT Receive Status (B2_L1RSUM_STA)       | This bit is set to 1 when PLL wakeup is requested (USB20_CON.B2_SUSPEND = 0 or B2_PLL_WAKEIN = 1) or when the resume request from USB2.0 host is received (USB_STA.B2_L1RSUM_OUT changes from 0 to 1) during L1 state (USB_STA.B2_L1_SPND_OUT = 1).                                                          |
| 9            | USB2 SPND_OUT Receive Status (B2_SPND_STA)            | This bit is set to 1 when the suspend request has been received from USB2.0 host (the device cannot deny it) and USB_STA.B2_SPND_OUT changes from 0 to 1.                                                                                                                                                    |
| 8            | USB2_RSUM_OUT Receive Status (B2_RSUM_STA)            | This bit is set to 1 when PLL wakeup is requested (USB20_CON.B2_SUSPEND = 0 or B2_PLL_WAKEIN = 1) or when the resume request from USB2.0 host is received (USB_STA.B2_RSUM_OUT changes from 0 to 1) during L2 state (USB_STA.B2_SPND_OUT = 1) or L3 state (USB20_CON.B2_CONNECT=0).                          |
| 7 to 2       | —                                                     | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                         |

(9) USB Interrupt Enable 2 Register (USB\_PERI\_USB\_INT\_ENA\_2)

This register is used to enable the interrupts of USB endpoints.

Access Size: 32 bits  
Address(es): <USB\_S1\_base> + 022Ch  
Initial Value: 0000\_0000h

Table 34.6-24 USB\_PERI\_USB\_INT\_ENA\_2 Register Contents

| Bit Position | Bit Name           | Description                                                                                                                                                                                                                |
|--------------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31           | —                  | Reserved. This bit is read as 0b.                                                                                                                                                                                          |
| 30 to 16     | —                  | Reserved. These bits are read as 0b. The write value should be 0b.                                                                                                                                                         |
| 15 to 0      | PIPE[15:0]_INT_ENA | This bit is used to enable an interrupt due to USB_INT_STA_2.PIPEi_INT_STA (i = 15 to 0).<br>1b: Interrupt due to USB_INT_STA_2.PIPEi_INT_STA is enabled.<br>0b: Interrupt due to USB_INT_STA_2.PIPEi_INT_STA is disabled. |

(10) Setup Data 0 Register (USB\_PERI\_STUP\_DAT\_0)

This register shows the first 4 bytes of setup data which has been received in control transfer.

Access Size: 32 bits  
Address(es): <USB\_S1\_base> + 0230h  
Initial Value: 0000\_0000h

|               |              |    |    |    |    |    |    |    |              |    |    |    |    |    |    |    |

| Bit Position | Bit Name     | Description                                  |
|--------------|--------------|----------------------------------------------|
| 31 to 24     | SETUP_7[7:0] | This field shows the 8th byte of setup data. |
| 23 to 16     | SETUP_6[7:0] | This field shows the 7th byte of setup data. |
| 15 to 8      | SETUP_5[7:0] | This field shows the 6th byte of setup data. |
| 7 to 0       | SETUP_4[7:0] | This field shows the 5th byte of setup data. |

(12) USB30 TP\_Send Data 0 Register (USB\_PERI\_USB3\_TPDAT\_0)

This register is used to set DWORD 0 of TP to be transmitted to USB3.1 host.

Access Size: 32 bits  
Address(es): <USB\_S1\_base> + 0240h  
Initial Value: 0000\_0000h

Table 34.6-27 USB\_PERI\_USB3\_TPDAT\_0 Register Contents

| Bit Position | Bit Name                            | Description                                                                          |

Table 34.6-31 USB\_PERI\_USB30\_VND\_DEV Register Contents

| Bit Position | Bit Name                                  | Description                                                                                                                                                                                                                                       |
|--------------|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 8      | —                                         | Reserved. These bits are read as 0b.                                                                                                                                                                                                              |
| 7 to 0       | Vendor Device Test Status (VND_DTST[7:0]) | This field indicates Vendor Device Test field of received Vendor Device Test LMP.<br>Check this field when an interrupt due to USB_INT_STA_1.B3_VNDTST_STA is asserted. This field is updated every time when Vendor Device Test LMP is received. |

(17) USB30 Vendor Defined Data 0 Register (USB\_PERI\_USB30\_VND\_DAT\_0)

This register shows Vendor Defined Data field in DWORD 1 of the received Vendor Device Test LMP.

Access Size: 32 bits  
Address(es): <USB\_S1\_base> + 0258h  
Initial Value: 0000\_0000h

Table 34.6-32 USB\_PERI\_USB30\_VND\_DAT\_0 Register Contents

| Bit Position | Bit Name                                         | Description                                                                                                                                                                                                                                                       |
|--------------|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | Vendor Defined Data 0 Register (VND_DAT_0[31:0]) | This field indicates Vendor Defined Data field in DWORD 1 of the received Vendor Device Test LMP.<br>Check this field when an interrupt due to USB_INT_STA_1.B3_VNDTST_STA is asserted. This field is updated every time when Vendor Device Test LMP is received. |

(18) USB30 Vendor Defined Data 1 Register (USB\_PERI\_USB30\_VND\_DAT\_1)

This register shows Vendor Defined Data field in DWORD 2 of the received Vendor Device Test LMP.

Access Size: 32 bits  
Address(es): <USB\_S1\_base> + 025Ch  
Initial Value: 0000\_0000h

Table 34.6-33 USB\_PERI\_USB30\_VND\_DAT\_1 Register Contents

| Bit Position | Bit Name                                         | Description                                                                                                                                                                                                                                                        |

Table 34.6-34 USB\_PERI\_USB\_VER Register Contents

| Bit Position | Bit Name                        | Description                                                                                                                     |
|--------------|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| 31           | AXI Mode (AXI_MODE)             | This field shows the AXI mode of register groups to have the information of PRD Table. In this unit, AXI Register Mode2 is used |
| 30 to 27     | —                               | Reserved. These bits are read as 0b.                                                                                            |
| 26 to 24     | Renesas Private                 | This field is read only. The initial value of this field is 100b, but it depends on setting of HW.                              |
| 23 to 21     | —                               | Reserved. These bits are read as 0b.                                                                                            |
| 20 to 16     | Number of PIPEs (PIPE_NUM[4:0]) | This field shows the number of PIPEs.                                                                                           |
| 15 to 8      | Major Version (MJR_VER[7:0])    | This field shows the major version of EPC .                                                                                     |
| 7 to 0       | Minor Version (MIN_VER[7:0])    | This field shows the minor version of EPC .                                                                                     |

(20) Scratch Pad Register (USB\_PERI\_USB\_SCRATCH)

This register provides the function of scratch pad. The main purpose of this register is debug use.

Access Size: 32 bits  
Address(es): <USB\_S1\_base> + 0264h  
Initial Value: 0000\_0000h

Table 34.6-35 USB\_PERI\_USB\_SCRATCH Register Contents

| Bit Position | Bit Name                    | Description                                                                                                                        |
|--------------|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | Scratch Pad (SCRATCH[31:0]) | This field is used as scratch pad. This field holds the written data and it can be read any time as long as USB3PERI is not reset. |

(21) PIPE0 Mode Setting Register (USB\_PERI\_P0\_MOD)

This register indicates the mode settings for PIPE0.

Access Size: 32 bits  
Address(es): <USB\_S1\_base> + 0280h  
Initial Value: 0000\_0000h

|               |    |    |    |    |    |    |    |    |    |        |    |    |    |    |    |    |

| 31 to 4      | —                                       | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 3            | PIPE0 Flow Control Status (P0_FLOWSTS)  | This bit shows the flow control status of PIPE0.<br>1b: Flow control state<br>0b: Normal state                                                                                                                                                                                                                                                                                                                                                                                                         |
| 2            | PIPE0 ACK_TP Receive Status (P0_ACKSTS) | This bit shows whether PIPE0 has data that is currently being transferred or not.<br>In case that the direction of transfer is OUT (P0_MOD.P0_DIR = 0), this bit shows 1b if PIPE0 has data which has been received but ACK for it has not been transmitted yet.<br>In case that the direction of transfer is IN (P0_MOD.P0_DIR = 1), this bit shows 1b if PIPE0 has data which has already been transmitted but has not received ACK for it yet.                                                      |
| 1            | PIPE0 Send Status (P0_SNDSTS)           | This bit shows 1b if PIPE0 has data which has not been transmitted yet.<br>This bit is reset to 0b when all of written data have been transmitted and ACKs for them have been received.<br>This bit is invalid for the case that the direction of transfer is OUT (P0_MOD.P0_DIR = 0).                                                                                                                                                                                                                 |
| 0            | PIPE0 Buffer Status (P0_BUFSTS)         | This bit shows the buffer status of PIPE0.<br>0: The buffer cannot accept data for write, or it has no packet for read.<br>1: the buffer can accept data for write, or it has one or more packets<br>For read, In case that the direction of transfer is OUT (P0_MOD.P0_DIR = 0), this bit shows 1 if it has one or more received packets in the buffer.<br>In case that the direction of transfer is IN (P0_MOD.P0_DIR = 1), this bit shows 1 if data to be transmitted can be written to the buffer. |

**Note:** Once the access to one of P0\_READ, Pn\_READ, P0\_WRITE and Pn\_WRITE registers is started in order to read or write a packet, it is prohibited to access to other Px\_yyy register before whole of a packet has been read or written with the register which is currently used. The access to these registers is controlled in a unit of a packet, so the targeted register can be changed at the point that the read or write of the current packet has been completed and the access for the next packet is not started yet.

**(24) PIPE0 Interrupt Status Register (USB\_PERI\_P0\_INT\_STA)**

This register shows the interrupt factors of EPC\_INTR\_P[0].

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + 0290h

**Initial Value:** 0000\_0000h

| Bit Position | Bit Name                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 10     | —                                  | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 9 to 0       | PIPE0 Data Length (P0_LENGTH[9:0]) | <p>This field shows the number of bytes in received packet which is currently read from P0_READ register.</p> <p>The value is decremented every time P0_READ register is read.</p> <p>Since P0_READ register allows only 32-bit access, the value is decremented by 4.</p> <p>Since P0_READ register is controlled in a unit of a packet, the length of received packet is shown in this register when the first 4 bytes of it are shown in P0_READ register and have not been read yet. This register is valid only for OUT direction.</p> |

**Note:** Once the access to one of P0\_READ, Pn\_READ, P0\_WRITE and Pn\_WRITE registers is started in order to read or write a packet, it is prohibited to access to other Px\_yyy register before whole of a packet has been read or written with the register which is currently used. The access to these registers is controlled in a unit of a packet, so the targeted register can be changed at the point that the read or write of the current packet has been completed and the access for the next packet is not started yet.

**(27) PIPE0 Read Register (USB\_PERI\_P0\_READ)**

This register is used to read OUT data which has been received at PIPE0.

If there is no data in buffer, 0000\_0000h is returned.

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + 02A4h

**Initial Value:** 0000\_0000h

Table 34.6-42 USB\_PERI\_P0\_READ Register Contents

| Bit Position | Bit Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | PIPE0 Read Data (P0_RDATA[31:0]) | <p>Read data from PIPE0.</p> <p>This register is controlled in a unit of a packet and cannot be read across the packet. That is, this register is updated in a unit of a packet. The current packet is never concatenated with the next packet even when the length of the current packet is not multiples of 4 and the last word of it is less than 4 bytes. In that case, the first 4 bytes of the next packet are shown in this register after the last word of the previous packet has been read.</p> <p>If the length of the current packet is not multiples of 4 and the last word of it is less than 4 bytes, the last word has one or more invalid bytes. In order to know how many valid bytes the last word has, see P0_LENGTH[7:0] before the read of the packet and calculate from it. The valid bytes are aligned from P0_RDATA[7:0].</p> <p>This register is valid only for OUT direction.</p> |

**Note:** Once the access to one of P0\_READ, Pn\_READ, P0\_WRITE and Pn\_WRITE registers is started in order to read or write a packet, it is prohibited to access to other Px\_yyy register before whole of a packet has been read or written with the register which is currently used. The access to these registers is controlled in a unit of a packet, so the targeted register can be changed at the point that the read or write of the current packet has been completed and the access for the next packet is not started yet.

**(28) PIPE0 Write Register (USB\_PERI\_P0\_WRITE)**

This register is used to write IN data which is to be transmitted from PIPE0.

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + 02A8h

**Initial Value:** 0000\_0000h

|               |                 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

**(31) PIPEn RAM Mapping Register (USB\_PERI\_Pn\_RAMMAP)**

This register is used to configure the mapping of SRAM for PIPEn.

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + 02C4h

**Initial Value:** 0000\_0000h

**(32) PIPEn Control Register (USB\_PERI\_Pn\_CON)**

This register provides control for PIPEn.

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + 02C8h

**Initial Value:** 0000\_0000h

|--------------|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 4      | —                                       | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 3            | PIPEn Flow Control Status (Pn_FLOWSTS)  | This bit shows the flow control state of PIPEn.<br>1b: Flow control state<br>0b: Normal state                                                                                                                                                                                                                                                                                                                                                                                                            |
| 2            | PIPEn ACK_TP Receive Status (Pn_ACKSTS) | This bit shows whether PIPEn has data that is currently being transferred or not.<br>In case that the direction of transfer is OUT (Pn_MOD.Pn_DIR = 0), this bit shows 1 if PIPEn has data which has been received but ACK for it has not been transmitted yet.<br>In case that the direction of transfer is IN (Pn_MOD.Pn_DIR = 1), this bit shows 1 if PIPEn has data which has already been transmitted but has not received ACK for it yet.                                                          |
| 1            | PIPEn Send Status (Pn_SNDSTS)           | This bit shows 1 if PIPEn has data which has not been transmitted yet.<br>This bit is reset to 0 when all of written data have been transmitted and ACKs for them have been received.<br>This bit is invalid for the case that the direction of transfer is OUT (Pn_MOD.Pn_DIR = 0).                                                                                                                                                                                                                     |
| 0            | PIPEn Buffer Status (Pn_BUFSTS)         | This bit shows the buffer status of PIPEn.<br>0b: The buffer cannot accept data for write, or it has no packet for read.<br>1b: The buffer can accept data for write, or it has one or more packets for read.<br>In case that the direction of transfer is OUT (Pn_MOD.Pn_DIR = 0), this bit shows 1 if it has one or more received packets in the buffer.<br>In case that the direction of transfer is IN (Pn_MOD.Pn_DIR = 1), this bit shows 1 if data to be transmitted can be written to the buffer. |

**Note:** Once the access to one of P0\_READ, Pn\_READ, P0\_WRITE and Pn\_WRITE registers is started in order to read or write a packet, it is prohibited to access to other Px\_yyy register before whole of a packet has been read or written with the register which is currently used. The access to these registers is controlled in a unit of a packet, so the targeted register can be changed at the point that the read or write of the current packet has been completed and the access for the next packet is not started yet.

**(34) PIPEn Interrupt Status Register (USB\_PERI\_Pn\_INT\_STA)**

This register indicates Interrupt factor of INTR\_Pn\_B Pin.

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + 02D0h

**Initial Value:** 0000\_0000h

| 16           | PIPEn Receive PRIME Status (Pn_PRIME_STA)     | <p>This bit indicates that PRIME is designated as Stream ID for PIPEn and is valid only in case Stream bulk protocol is used (Pn_MOD.Pn_STREAM = 1).</p> <p>In case the direction of transfer is IN (Pn_MOD.Pn_DIR = 1), this bit is set when ACK(PRIME) is received. Pn_CON.Pn_RES[1:0] is automatically set to NRDY response (= 00b) in that case.</p> <p>In case the direction of transfer is OUT (Pn_MOD.Pn_DIR = 0), this bit is set when DP(PRIME) is received. Pn_CON.Pn_ERS[1:0] is automatically set to NRDY response (= 00b) in that case.</p> <p>This bit is invalid in case of HS/FS.</p>                                           |
| 15 to 9      | —                                             | Reserved. These bits are read as 0b. Writing is invalid.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 8            | PIPEn Receive Null Data Status (Pn_RCVNL_STA) | <p>This bit indicates that zero length packet has been received at PIPEn and becomes ready to be read.</p> <p>The zero length packet received is automatically discarded when Pn_LNG register is read for it. Therefore, this bit is asserted when Pn_LNG register shows 0 for the zero length packet received.</p> <p>When this bit is asserted, it is required to read Pn_LNG register as the read action for the zero length packet. If Pn_LNG register shows 0, it means the zero length packet has been read.</p>                                                                                                                          |
| 7            | PIPEn ERDY_TP Send Status (Pn_ERDY_STA)       | <p>This bit indicates that the condition to transmit ERDY from PIPEn is satisfied.</p> <p>If Pn_CON.Pn_RES[1:0] has the value other than NRDY response and this bit is asserted, ERDY is transmitted to host.</p> <p>For Stream bulk protocol, Pn_CON.Pn_RES[1:0] should be set to normal response (= 01b) so that ERDY is transmitted to specify Stream ID.</p> <p>This bit is invalid in case of HS and FS.</p>                                                                                                                                                                                                                               |
| 6            | PIPEn Flow Control Status (Pn_FLOW_STA)       | <p>This bit indicates that PIPEn enters the flow control state.</p> <p>In case the direction of transfer is IN (Pn_MOD.Pn_DIR = 1), this bit is set to 1 when PIPEn sends NRDY or DP with EOB = 1.</p> <p>In case the direction of transfer is OUT (Pn_MOD.Pn_DIR = 0), this bit is set to 1 when PIPEn sends NRDY or ACK with NumP = 0.</p> <p>This bit is also set to 1 when PIPEn receives the deferred packet. But this bit is not set to 1 in the case of received SETUP DP (deferred = 1) etc. It is recommended to use bit[5] to detect the deferred packet.</p> <p>This bit is invalid in case of HS and FS.</p>                        |
| 5            | PIPEn Deferred Status (Pn_DF_STA)             | <p>This bit indicates that PIPEn receives the deferred packet.</p> <p>This bit is set to 1 when PIPEn receives the deferred packet.</p> <p>This bit is invalid in case of HS and FS.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 4            | PIPEn Last Transaction Status (Pn_LSTTR_STA)  | <p>This bit indicates that PIPEn has transmitted or received the last packet of the transfer.</p> <p>In case the direction of transfer is IN (Pn_MOD.Pn_DIR = 1), this bit is set to 1 when PIPEn has transmitted the packet for which Pn_CON.Pn_LAST is set.</p> <p>In case the direction of transfer is OUT (Pn_MOD.Pn_DIR = 0), this bit is set to 1 when PIPEn has received the short packet or the packet with PP = 0.</p>                                                                                                                                                                                                                 |
| 3            | —                                             | Reserved. This bit is read as 0b.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 2            | PIPEn STALL Response Status (Pn_STALL_STA)    | This bit is set to 1 when STALL has been transmitted from PIPEn.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 1            | PIPEn NRDY_TP Response Status (Pn_NRDY_STA)   | This bit is set to 1 when NRDY or NAK has been transmitted from PIPEn.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 0            | PIPEn Buffer Ready Status (Pn_BFRDY_STA)      | <p>This bit indicates the buffer status of PIPEn.</p> <p>In case the direction of transfer is IN (Pn_MOD.Pn_DIR = 1), this bit is set to 1 when the buffer of PIPEn is ready to accept the next IN data. This bit is not asserted for the write of first packet after USB3PERI is initialized by a reset (hardware reset, USB_COM_CON.PIPE_CLR, Pn_CON.Pn_BCLR and Pn_CON.Pn_CLR). After a reset, the first packet can be written immediately although this bit is not asserted.</p> <p>In case the direction of transfer is OUT (Pn_MOD.Pn_DIR = 0), this bit is set to 1 when the next packet in the buffer of PIPEn is ready to be read.</p> |

**Note:** These bits are cleared by writing 1.

**(35) PIPEn Interrupt Enable Register (USB\_PERI\_Pn\_INT\_ENA)**

This register is used to enable the interrupts related to PIPEn.

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + 02D4h

**Initial Value:** 0000\_0000h

Table 34.6-51 USB\_PERI\_Pn\_RSVPKT Register Contents

| Bit Position | Bit Name                                      | Description                                                                                                                                      |
|--------------|-----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 5      | —                                             | Reserved. These bits are read as 0b.                                                                                                             |
| 4 to 0       | PIPEn Reserved Packet Number (Pn_RSVPKT[4:0]) | This field shows the number of packets that are not transmitted yet in the buffer of PIPEn (n is 0 to 15). This field is valid only for IN PIPE. |

**Note:** Once the access to one of P0\_READ, Pn\_READ, P0\_WRITE and Pn\_WRITE registers is started in order to read or write a packet, it is prohibited to access to other Px\_yyy register before whole of a packet has been read or written with the register which is currently used. The access to these registers is controlled in a unit of a packet, so the targeted register can be changed at the point that the read or write of the current packet has been completed and the access for the next packet is not started yet.

**(37) PIPEn Length Register (USB\_PERI\_Pn\_LNG)**

This register shows the number of bytes in received packet which is currently read from Pn\_READ register.

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + 02E0h

**Initial Value:** 0000\_0000h

Table 34.6-52 USB\_PERI\_Pn\_LNG Register Contents

| Bit Position | Bit Name                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 16     | —                                   | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 15 to 0      | PIPEn Data Length (Pn_LENGTH[15:0]) | <p>This field shows the number of bytes in received packet which is currently read from Pn_READ register.</p> <p>The value is decremented every time Pn_READ register is read.</p> <p>Since Pn_READ register allows only 32-bit access, the value is decremented by 4.</p> <p>Since Pn_READ register is controlled in a unit of a packet, the length of received packet is shown in this register when the first 4 bytes of it are shown in Pn_READ register and have not been read yet.</p> <p>This field is valid only for OUT PIPE.</p> |

**Note:** Once the access to one of P0\_READ, Pn\_READ, P0\_WRITE and Pn\_WRITE registers is started in order to read or write a packet, it is prohibited to access to other Px\_yyy register before whole of a packet has been read or written with the register which is currently used. The access to these registers is controlled in a unit of a packet, so the targeted register can be changed at the point that the read or write of the current packet has been completed and the access for the next packet is not started yet.

**(38) PIPEn Read Register (USB\_PERI\_Pn\_READ)**

This register is used to read OUT data which has been received at PIPEn.

If there is no data in buffer, 0000\_0000h is returned.

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + 02E4h

**Initial Value:** 0000\_0000h

Table 34.6-53 USB\_PERI\_Pn\_READ Register Contents

| Bit Position | Bit Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | PIPEn Read Data (Pn_RDATA[31:0]) | <p>Read data from PIPEn.</p> <p>This register is controlled in a unit of a packet and cannot be read across the packet.</p> <p>That is, this register is updated in a unit of a packet. The current packet is never concatenated with the next packet even when the length of the current packet is not multiples of 4 and the last word of it is less than 4 bytes. In that case, the first 4 bytes of the next packet are shown in this register after the last word of the previous packet has been read.</p> <p>If the length of the current packet is not multiples of 4 and the last word of it is less than 4 bytes, the last word has one or more invalid bytes. In order to know how many valid bytes the last word has, see Pn_LENGTH[7:0] before the read of the packet and calculate from it. The valid bytes are aligned from Pn_RDATA[7:0].</p> <p>This register is valid only for OUT PIPE</p> |

**Note:** Once the access to one of P0\_READ, Pn\_READ, P0\_WRITE and Pn\_WRITE registers is started in order to read or write a packet, it is prohibited to access to other Px\_yyy register before whole of a packet has been read or written with the register which is currently used. The access to these registers is controlled in a unit of a packet, so the targeted register can be changed at the point that the read or write of the current packet has been completed and the access for the next packet is not started yet.

**(39) PIPEn Write Register (USB\_PERI\_Pn\_WRITE)**

This register is used to write IN data which is to be transmitted from PIPEn.

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + 02E8h

**Initial Value:** 0000\_0000h

| 31 to 0      | PIPEn Write Data (Pn_WDATA[31:0]) | <p>Write data to PIPEn.</p> <p>This register is controlled in a unit of a packet and cannot be written across the packet. That is, it is not allowed to concatenate the current packet with the next packet to write them to this register even when the length of the current packet is not multiples of 4 and the last word of it is less than 4 bytes. In that case, the next packet can be written to this register after the write of the previous packet has been completed and it has been transmitted.</p> <p>This register is valid only for IN PIPE.</p> |

**Note:** Once the access to one of P0\_READ, Pn\_READ, P0\_WRITE and Pn\_WRITE registers is started in order to read or write a packet, it is prohibited to access to other Px\_yyy register before whole of a packet has been read or written with the register which is currently used. The access to these registers is controlled in a unit of a packet, so the targeted register can be changed at the point that the read or write of the current packet has been completed and the access for the next packet is not started yet.

**(40) PIPEn Stream ID Register (USB\_PERI\_Pn\_STREAMID)**

This register is used to set Stream ID for PIPEn for Stream bulk protocol.

Always set Pn\_STREAMID[15:0] to 0000h.

**Access Size:** 32 bits

**Address(es):** <USB\_S1\_base> + 02F0h

**Initial Value:** 0000\_0000h

| 31 to 16     | PIPEn Stream ID (Pn_STREAM_C [15:0])      | <p>This field indicates the Stream ID that is currently valid.</p> <p>This field is invalid in case of HS/FS.</p> <p>This field is valid only in case that the type of transfer is bulk (Pn_TYPE = 10b) and Stream ID is supported (Pn_MOD.Pn_STREAM = 1) for PIPEn.</p> <p>When this field shows 0000h, it means that Stream ID is not set yet.</p> <p>This field is reset when Pn_CON.Pn_BCLR is set.</p>                                                                     |
| 15 to 0      | PIPEn Next Stream ID (Pn_STREAM_N [15:0]) | <p>This field indicates the Stream ID to be used in the next transfer at PIPEn.</p> <p>This field is invalid in case of HS/FS.</p> <p>This field is valid only in case that the type of transfer is bulk (Pn_TYPE = 10b) and Stream ID is supported (Pn_MOD.Pn_STREAM = 1) for PIPEn.</p> <p>When Pn_STREAM_C[15:0] is switched to the ID in this field, this field is reset to 0000h.</p> <p>Make sure to confirm that this field is reset to 0000h before setting new ID.</p> |

(41) PIPEn NRDY Stream ID Register (USB\_PERI\_Pn\_NRDYSTRM)

This register shows Stream ID which was requested from host but responded with NRDY at PIPEn.

USB3PERI responds with NRDY for the Stream ID which is not equal to the current Stream ID in Pn\_STREAM register.

(2) Port PM Status and Control Register (USB\_PERI\_PORTPMSC)

This register contains the status bits for the Force Link PM Accept bit and the timeout values for the U1 and U2 inactivity timers.

Access Size: 32 bits  
Address(es): <USB\_S1\_base> + 0304h  
Initial Value: 0000\_0000h

| Bit Position | Bit Name                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 17     | —                          | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 16           | Force Link PM Accept (FLA) | <p>This bit is set to 1b when Force LinkPM Accept bit in the received Set Link Function LMP equals to 1b.</p> <p>In case this bit shows 1, the port accepts LGO_U1 and LGO_U2 with no condition.</p> <p>This bit is cleared to 0 when Set Link Function LMP with Force LinkPM Accept bit = 0 is received.</p> <p>Software can write 0 to clear this bit (To write 1 is ignored), but basically this bit is set or reset on the reception of Set Link Function LMP.</p> |

Table 34.6-58 USB\_PERI\_PORTPMSC Register Contents (2/2)

| Bit Position | Bit Name                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15 to 8      | U2 Timeout<br>(U2_TIMEOUT[7:0]) | <p>This field indicates the timeout value in the U2 inactivity timer.</p> <p>00h: No timeout but LGO_Ux is always denied with LXU : default</p> <p>01h: 256 us</p> <p>02h: 512 us</p> <p> </p> <p>FEh: 65.204 ms</p> <p>FFh: No timeout and LGO_Ux is basically accepted.</p> <p>(But it might be rejected due to other reasons.)</p> <p>This field is automatically updated when U2 Inactivity LMP is received.</p> <p>When this field has the value from 01h to FEh, it means the idle timeout value for LTSSM to request the transition from U0 state to U2 state as well as the idle timeout value for to make the transition from U1 state to U2 state.</p> <p>If U1_TIMEOUT[7:0] has 00h or FFh but U2_TIMEOUT[7:0] has a value from 01h to FEh, U2 timeout occurs although U1 timeout never. In that case USB3PERI never sends LGO_U1 but sends LGO_U2 to request the transition from U0 state to U2 state. If downstream port accepts the request, the downstream port and USB3PERI enter U2 state.</p> <p>Otherwise, U1 timeout occurs first and USB3PERI sends LGO_U1 to request the transition from U0 state to U1 state. If downstream port accepts the request, the downstream port and USB3PERI enter U1 state. If they stay in U1 state and U2 timeout occurs, they make the transition from U1 state to U2 state silently, without going back to U0 state.</p> <p>The transition is executed automatically by hardware when the timeout occurs.</p> <p><i>Note:</i> This field is initialized to 00h during reset and just after a reset, but changed to FFh when USB3PERI detects a disconnection from USB3.1 device. If reset (in this case, it will be power on reset) is asserted but the device is in the disconnected state, FFh might be loaded to this field. Since this field is changed to FFh when a disconnection is detected, set the adequate value to this field after the connection if required.</p> |
| 7 to 0       | U1 Timeout<br>(U1_TIMEOUT[7:0]) | <p>This field indicates the timeout value in the U1 inactivity timer.</p> <p>00h: No timeout but LGO_Ux is always denied with LXU: default</p> <p>01h: 1 us</p> <p>02h: 2 us</p> <p> </p> <p>7Fh: 127 us</p> <p>80h-FEh: Reserved</p> <p>FFh: No timeout and LGO_Ux is basically accepted.</p> <p>(But it might be rejected due to other reasons.)</p> <p>This field is not automatically updated unlike U2_TIMEOUT[7:0]. Software is required to set this field.</p> <p>When this field has the value from 01h to 7Fh, it means the idle timeout value for LTSSM to request the transition from U0 state to U1 state. The hardware automatically sends LGO_U1 when the timeout occurs. If it is accepted, the transition is also executed by hardware automatically.</p> <p><i>Note:</i> This field is initialized to 00h during a reset and just after a reset, but changed to FFh when USB3PERI detects a disconnection from USB3.1 device. If reset (in this case, it will be power on reset) is asserted but the device is in the disconnected state, FFh might be loaded to this field. Since this field is changed to FFh when a disconnection is detected, set the adequate value to this field after the connection if required.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

(3) Port Link Information Register (USB\_PERI\_PORTLI)

This register indicates the number of errors detected.

Access Size: 32 bits  
Address(es): <USB\_S1\_base> + 0308h  
Initial Value: 0000\_0000h

### 34.6.4 Details of Functions

This section describes the functions of USB3PERI.

The prefix (USB\_PERI\_) of the register names is omitted in this and subsequent sections.

#### 34.6.4.1 VBUS Connection

VBUS is the power supply signal from USB host or hub, device can know that it is connected to host or hub when VBUS is asserted. But since VBUS input might be unstable just after device is connected, device should wait for a certain time till it becomes stable especially if it is bus-powered device. In order to control the interval from the assertion of VBUS to the time VBUS becomes stable, VBUS signal is not directly connected to link layer (ssif\_us) but USB30\_CON.B3\_CONNECT is connected to it instead. The value of the bit is output to link layer which sees the value to know whether it is being connected or not. This mechanism enables that firmware inserts the wait time between when it detects the assertion of VBUS by USB\_INT\_STA\_1.VBUS\_CNG\_STA and when it sets USB30\_CON.B3\_CONNECT.

In the same way, VBUS signal is not directly connected to some modules of USB3PERI and USB2.0-PHY but USB20\_CON.B2\_CONNECT is used to notify them that device is connected.

#### NOTE

VBUS or USB30\_CON.B3\_CONNECT is not provided directly to USB3.1-PHY. USB3.1-PHY that is provided from Renesas is designed not to see the state of VBUS but to follow the instruction of power down from upper layer on POWERDOWN[1:0] for its power management. But some USB2.0-PHYs that is provided from Renesas are designed to see the state of VBUS and require that VBUS or similar signal is connected.

When device is in suspended state or unconnected, PLLs in USB3.1-PHY and USB2.0-PHY can be stopped in order to reduce their power consumptions. But if the device is disconnected when it is in suspended state, it means that the request to wake up from host never comes any more. In such case, it might be required to resume PLLs if they have been stopped so that device initializes by itself and prepares for the next connection. On the other hand, device might be required to resume PLLs if they have been stopped in unconnected state but device detects the connection. The state of connection or disconnection can be known on VBUS state. The change of VBUS state is notified on USB\_INT\_STA\_1.VBUS\_CNG\_STA. As shown in the cases above, the software is required to control PLLs in USB3.1-PHY and USB2.0-PHY depending on VBUS state.

### 34.6.4.2 USB3.1/USB2.0 connection

In this section the outline of USB3.1 and USB2.0 connection in USB3.1 specification is explained. See **Section 34.6.5.3(6), USB2.0 Bus Reset Process** for details of the software flow.

The behavior of peripheral device upstream port state machine is described in 10.18.2 of USB3.1 specification Revision 1.0 July 26, 2013.

Figure 34.6-4 Peripheral Upstream Device Port State Machine (from Figure10-26 in USB3.1 specification)

As initial state, in which VBUS is off, the upstream port of the device is in USDPORT.Powered-off. The port should have the variable “DisabledCount” to control the transition to or from USDPORT.Disabled. The DisabledCount should be initialized to 0 when power is off or when the port’s link completes the port configuration.

When VBUS becomes valid (on), the port transits to USDPORT.Powered on. In this state, the port’s link is in Rx.Detect. On this first entry to USDPORT.Powered on, the port’s link makes the trial of Rx detection up to 8. If it detects Far End Receiver Termination of the link partner, the upstream port enters USDPORT.Training, and after the training has successfully completed it enters USDPORT.Connected/Enabled.

But if the port fails in the port configuration, it enters USDPORT.Disabled.

But if the port’s link cannot detect Far End Receiver Termination even when it tries 8 times, the port enters USDPORT.Disabled. With this transition DisabledCount is incremented if it is less than 3. In this state, the function of USB3.1 is disabled once and the function of USB2.0 starts working.

If downstream port detects D+ line is pulled up, it recognizes the device wants to be connected as USB2.0 device. The downstream port asserts USB2.0 bus reset to start the process of USB2.0 connection.

Receiving USB2.0 bus reset, the upstream port returns to USDPORT.Powered on. On this entry to USDPORT.Powered on, the function of USB3.1 is enabled again and the port’s link makes the trial of Rx detection only one time. Note that the pull-up of D+ line is still enabled and the process of USB2.0 connection is still valid.

If the port’s link detects Far End Receiver Termination of the link partner, the upstream port enters USDPORT.Training and the connection as USB2.0 device is disabled within tUSB2SwitchDisconnect ( = 1ms). If the port succeeds in the training, it enters USDPORT.Connected/Enabled.

But if the port’s link cannot detect Far End Receiver Termination, the function of USB3.1 is disabled again. When the port succeeds in USB2.0 connection, the device works in HS or FS of USB2.0. With this failure of Rx detection, the port enters USDPORT.Disabled as USB3.1 port and DisabledCount is incremented if it is less than 3.

If DisabledCount equals to 3 when the port enters USDPORT.Disabled, it makes the transition to USDPORT.Disabled\_Error.

Whenever the port is in USDPORT.Disabled and USB2.0 bus reset comes, the port transits to USDPORT.Powered on and Rx detection for USB3.1 connection is started one time. Pull up of D+ can be seen from downstream port and USB2.0 connection is still active.

But if the port is in USDPORT.Disabled\_Error when USB2.0 bus reset comes, it tries Rx detection no more and can only executes USB2.0 connection. Since DisabledCount is initialized to 0 when power is off or when the port configuration is completed, the port can exit from the state only when the power is removed.

### 34.6.4.3 Power Management Control

#### (1) USB3.1 Power Control

Table 34.6-63 USB3.1 Power Management

| LTSSM State               | USB3.1 PHY POWERDOWN | PLL Operation | Note                                                                          |
|---------------------------|----------------------|---------------|-------------------------------------------------------------------------------|
| SS.Disabled               | P2                   | Running       | Default                                                                       |
|                           | P0/P2                | Running       | The setting on USB30_CON.POW_SEL[2:0] is required.                            |
|                           | P3                   | Stopped       | The setting on USB30_CON.POW_SEL[2:0] is required.                            |
| Rx.Detect                 | P2                   | Running       |                                                                               |
| U0                        | P0                   | Running       |                                                                               |
| U1                        | P1                   | Running       |                                                                               |
| U2                        | P2                   | Running       |                                                                               |
| U3                        | P0/P2                | Running       | Default<br>Select P0 or P2 as the initial state on USB30_CON.U3_POW_SEL[1:0]. |
|                           | P0/P2                | Running       | The setting on USB30_CON.POW_SEL[2:0] is required.                            |
|                           | P3                   | Stopped       | The setting on USB30_CON.POW_SEL[2:0] is required.                            |
| U3 -> U3_Wakeup,Reset     | P0                   | Running       | Transition due to the reception of LFPS from host                             |
| U3 (P0/2) -> RemoteWakeup | P0                   | Running       | The setting on PORTSC.PLS[3:0] is required after waking up PLL in USB3.1-PHY. |
| U3(P3) -> RemoteWakeup    | P0                   | Running       | The setting on USB30_CON.POW_SEL[2:0] is required.                            |
| Others                    | P0                   | Running       |                                                                               |

Table 34.6-64 USB3.1 Power Management and Configured State

| Configured/Unconfigured (CONF) | USB3.1 PHY POWERDOWN | CLK Gating |         |         | Note                             |
|--------------------------------|----------------------|------------|---------|---------|----------------------------------|

| Unconfigured                   | P0/P1/P2             | Stopped    | Running | Running | Only PIPE0 is accessible in EPC. |
| (CONF = 0)                     | P3                   | Stopped    | Stopped | Running | PLL stopped                      |
| Configured                     | P0/P1/P2             | Running    | Running | Running | All PIPEs are accessible in EPC  |
| (CONF = 1)                     | P3                   | Stopped    | Stopped | Running | PLL Stopped                      |

[The behavior of PHY\_POWERDOWN[1:0] in Disconnected state (SS.Disabled)]

- P2 is designated on PHY\_POWERDOWN[1:0] with default setting.
- P0 or P3 is selectable as the request on PHY\_POWERDOWN[1:0] with the setting of USB30\_CON.POW\_SEL[2:0].

[The behavior of PHY\_POWERDOWN[1:0] in U3 state]

- P0 or P2 is designated on PHY\_POWERDOWN[1:0] depending on the setting of USB30\_CON.POW\_SEL[2:0].
- In order to place PHY in U3 state, the additional operation is required. See **Section 34.6.5.8(1), Suspend in USB3.1 (Transition of State from U0 to U3)** for details.

[In case of recovery from P3 (CLK125 is stopped in P3)]

- Transition from P3 to P0 can be requested on USB30\_CON.B3\_PLLWAKE or B3\_PLL\_WAKEIN signal.  
See **Section 34.6.5.8(6), USB3.1-PHY (PLL) Wakeup Process** for details.

## (2) USB3.1 Power State Control

### (a) In case downstream port requests the transition from U0 to U1

When LGO\_U1 comes as the request of transition to U1 state from the downstream port, USB3PERI decides whether it accepts or not depending on the setting in registers and the internal status.

There are two fields in registers related to accepting LGO\_U1, SSIFCMD.SSIF\_URES[0] and USB30\_CON.LPS\_ENABLE[1:0].

SSIFCMD.SSIF\_URES[0] is referred first in the decision whether LGO\_U1 is accepted or not. If SSIFCMD.SSIF\_URES[0] = 1 (forced LXU response), LGO\_U1 is rejected and USB3PERI returns LXU. If SSIFCMD.SSIF\_URES[0] = 0 (normal response), USB30\_CON.LPS\_ENABLE[1:0] is referred next.

If USB30\_CON.LPS\_ENABLE[1:0] = 10b (forced rejected), LGO\_U1 is rejected and USB3PERI returns LXU. If USB30\_CON.LPS\_ENABLE[1:0] = 01b (forced accepted), LGO\_U1 is accepted and USB3PERI returns LAU. If USB30\_CON.LPS\_ENABLE[1:0] = 00b (basically accepted), it depends on the internal status of USB3PERI whether it accepts LGO\_U1 or not.

With USB30\_CON.LPS\_ENABLE[1:0] = 00b, LGO\_U1 is rejected and USB3PERI returns LXU if one of the conditions below is satisfied. Otherwise, it is accepted and USB3PERI returns LAU.

- USB3PERI is still in U0 state
- 500 ms has not passed yet or the response from host has not come from the time when USB3PERI sends ERDY.
- ACK has not been received for the transmitted DP.
- IN PIPE has one or more packets to be transmitted in buffer.
- PP is 1 in the last packet received at OUT PIPE.

Figure 34.6-5 The Decision Flow Whether the Transition Request to U1 is Accepted or Not

**(b) In case device requests the transition from U0 to U1**

On the timeout of PORTPMSC.U1\_TIMEOUT[15:0], USB3PERI requests the transition from U0 state to U1 state. But it depends on the setting in registers and the internal status of USB3PERI whether it really requests the transition from U0 state to U1 state.

There are two fields in registers related to sending LGO\_U1, SSIFCMD.SSIF\_UREQ[0] and USB30\_CON.LPS\_ENABLE[1:0].

SSIFCMD.SSIF.UREQ[0] is referred first in the decision whether LGO\_U1 is sent or not. If SSIFCMD.SSIF.UREQ[0] = 1, LGO\_U1 isn't sent and USB3PERI never requests the transition from U0 state to U1 state. If SSIFCMD.SSIF.UREQ[1] = 0, USB30\_CON.LPS\_ENABLE[1:0] is referred next.

If USB30\_CON.LPS\_ENABLE[1:0] = 10b (forced rejected), LGO\_U1 isn't sent and USB3PERI never requests the transition from U0 state to U1 state. If USB30\_CON.LPS\_ENABLE[1:0] = 01b (forced accepted), LGO\_U1 is sent and USB3PERI requests the transition from U0 state to U1 state on the timeout of PORTPMSC.U1\_TIMEOUT[15:0]. If USB30\_CON.LPS\_ENABLE[1:0] = 00b (basically accepted), it depends on the internal status of USB3PERI whether it sends LGO\_U1 or not.

With USB30\_CON.LPS\_ENABLE[1:0] = 00b, LGO\_U1 isn't sent even when the timeout of PORTPMSC.U1\_TIMEOUT[15:0] occurs if one of the conditions below is satisfied. Otherwise, LGO\_U1 is sent and USB3PERI requests the transition from U0 to U1 on the timeout of PORTPMSC.U1\_TIMEOUT[15:0].

- USB3PERI is still in U0 state.
- 500 ms has not passed yet or the response from host has not come from the time when USB3PERI sends ERDY.
- ACK has not been received for the transmitted DP.
- IN PIPE has one or more packets to be transmitted in buffer.
- PP is 1 in the last packet received at OUT PIPE.

Figure 34.6-6 The Decision Flow Whether the Request of the Transition from U0 to U1 is Sent or Not

It is also available to use PORTPSC.PLS[3:0] in order to send LGO\_U1 at any point the software wants. See **Section 34.6.5.8(11), Process of Transition from U0 to U1/U2 in USB3.1 (Initiated by Device)** for details.

**(c) In case downstream port requests the transition from U1 to U0**

When the downstream port wants to exit from U1 state and U1 Exit LFPS comes, USB3PERI automatically responds to it and returns to U0 state.

At that time, USB\_INT\_STA\_1.B3\_LNKCNG\_STA is asserted and an interrupt due to it is asserted if enabled. PORTSC.PLS[3:0] shows U0 state (= 0h) after USB\_INT\_STA\_1.B3\_LNKCNG\_STA is asserted.

**(d) In case device requests the transition from U1 to U0**

USB3PERI automatically requests the exit from U1 state to the downstream port by sending U1 Exit LFPS when one of the conditions below is satisfied.

- when USB3PERI wants to send ERDY for the next transfer
- when USB3PERI wants to send the transaction packet written in USB3\_TPDAT\_x registers

In the first case, USB3PERI sends ERDY when the packet to be transmitted is prepared in buffer for IN PIPE and when the PIPE becomes ready to receive the next packet (Pn\_CON.Pn\_RES[1:0] is changed from 00b to 01b, for example) for OUT PIPE.

In the second case, USB3PERI sends the transaction packet in USB3\_TPDAT\_x registers when USB30\_CON.B3\_TP\_SEND is set to 1.

For both cases, the operations to send packet or start transfer are required, but there is no additional operation to exit from U1 state. Therefore, it is not required for user to mind whether the link is in U1 state or not before sending packet or starting transfer.

**(e) In case downstream port requests the transition from U0 to U2**

When LGO\_U2 as the request of transition to U2 state from the downstream port comes, USB3PERI decides whether it accepts or not depending on the setting in registers and the internal status.

There are two fields in registers related to accepting LGO\_U2, SSIFCMD.SSIF\_URES[1] and USB30\_CON.LPS\_ENABLE[1:0].

SSIFCMD.SSIF.URES[1] is referred first in the decision whether LGO\_U2 is accepted or not. If SSIFCMD.SSIF.URES[1] = 1 (forced LXU response), LGO\_U2 is rejected and USB3PERI returns LXU. If SSIFCMD.SSIF.URES[1] = 0 (normal response), USB30\_CON.LPS\_ENABLE[1:0] is referred next.

If USB30\_CON.LPS\_ENABLE[1:0] = 10b (forced rejected), LGO\_U2 is rejected and USB3PERI returns LXU. If USB30\_CON.LPS\_ENABLE[1:0] = 01b (forced accepted), LGO\_U2 is accepted and USB3PERI returns LAU. If USB30\_CON.LPS\_ENABLE[1:0] = 00b (basically accepted), it depends on the internal status of USB3PERI whether it accepts LGO\_U2 or not.

With USB30\_CON.LPS\_ENABLE[1:0] = 00b, LGO\_U2 is rejected and USB3PERI returns LXU if one of the conditions below is satisfied. Otherwise, it is accepted and USB3PERI returns LAU.

- USB3PERI is still in U0 state.
- 500 ms has not passed yet or the response from host has not come from the time when USB3PERI sends ERDY.
- ACK has not been received for the transmitted DP.
- IN PIPE has one or more packets to be transmitted in buffer.
- PP is 1 in the last packet received at OUT PIPE.

Figure 34.6-7 The Decision Flow Whether the Transition Request to U2 is Accepted or Not

#### (f) In case device requests the transition from U0 to U2

On the timeout of PORTPMSC.U2\_TIMEOUT[15:0], USB3PERI requests the transition from U0 state to U2 state. But it depends on the setting in registers and the internal status of USB3PERI whether it really requests the transition from U0 state to U2 state.

But the timeout value in U1\_TIMEOUT[15:0] is smaller than that in U2\_TIMEOUT[15:0] in general. In that case, U1 timeout occurs first, then U2 timeout occurs next if the device is still in U1 state. See **Section 34.6.4.3(2)(g), In case device requests the transition from U1 to U2** for the case.

There are two fields in registers related to sending LGO\_U2, SSIFCMD.SSIF\_UREQ[1] and USB30\_CON.LPS\_ENABLE[1:0].

SSIFCMD.SSIF\_UREQ[1] is referred first in the decision whether LGO\_U2 is sent or not. If SSIFCMD.SSIF\_UREQ[1] = 1, LGO\_U2 isn't sent and USB3PERI never requests the transition from U0 state to U2 state. If SSIFCMD.SSIF\_UREQ[1] = 0, USB30\_CON.LPS\_ENABLE[1:0] is referred next.

If USB30\_CON.LPS\_ENABLE[1:0] = 10b (forced rejected), LGO\_U2 isn't sent and USB3PERI never requests the transition from U0 state to U2 state. If USB30\_CON.LPS\_ENABLE[1:0] = 01b (forced accepted), LGO\_U2 is sent and USB3PERI requests the transition from U0 state to U2 state on the timeout of PORTPMSC.U2\_TIMEOUT[15:0]. If USB30\_CON.LPS\_ENABLE[1:0] = 00b (basically accepted), it depends on the internal status of USB3PERI whether it sends LGO\_U2 or not.

With USB30\_CON.LPS\_ENABLE[1:0] = 00b, LGO\_U2 isn't sent even when the timeout of PORTPMSC.U2\_TIMEOUT[15:0] occurs. If one of the conditions below is satisfied. Otherwise, LGO\_U2 is sent and USB3PERI requests the transition from U0 to U2 on the timeout of PORTPMSC.U2\_TIMEOUT[15:0].

- USB3PERI is still in U0 state.
- 500 ms has not passed yet or the response from host has not come from the time when USB3PERI sends ERDY.
- ACK has not been received for the transmitted DP.

- IN PIPE has one or more packets to be transmitted in buffer.
- PP is 1 in the last packet received at OUT PIPE.

Figure 34.6-8 The Decision Flow Whether the Request of the Transition from U0 to U2 is Sent or Not

#### (g) In case device requests the transition from U1 to U2

As explained in **Section 34.6.4.3(2)(f)**, In case device requests the transition from U0 to U2, when USB3PERI is in U1 state and the timeout of PORTPMSC.U2\_TIMEOUT[15:0] occurs, USB3PERI transits from U1 state to U2 state without returning to U0 state. In that case, it is required that SSIFCMD.SSIF\_UREQ[1] is set to 0.

#### (h) In case downstream port requests the transition from U2 to U0

When the downstream port wants to exit from U2 state and U2 Exit LFPS comes, USB3PERI automatically responds to it and returns to U0 state.

At that time, USB\_INT\_STA\_1.B3\_LNKCNG\_STA is asserted and an interrupt due to it is asserted if enabled. PORTSC.PLS[3:0] shows U0 state (= 0h) after USB\_INT\_STA\_1.B3\_LNKCNG\_STA is asserted.

**(i) In case device requests the transition from U2 to U0**

USB3PERI automatically requests the exit from U2 state to the downstream port by sending U2 Exit LFPS when one of the conditions below is satisfied.

- when USB3PERI wants to send ERDY for the next transfer
- when USB3PERI wants to send the transaction packet written in USB3\_TPDAT\_x registers

In the first case, USB3PERI sends ERDY when the packet to be transmitted is prepared in buffer for IN PIPE and when the PIPE becomes ready to receive the next packet (Pn\_CON.Pn\_RES[1:0] is changed from 00b to 01b, for example) for OUT PIPE.

In the second case, USB3PERI sends the transaction packet in USB3\_TPDAT\_x registers when USB30\_CON.B3\_TP\_SEND is set to 1.

For both cases, the operation to send packet or start transfer is required, but there is no additional operation to exit from U2 state. Therefore, it is not required for user to mind whether the link is in U1 state or not before sending packet or starting transfer.

**(j) In case downstream port requests the transition from U0 to U3**

Only downstream port can initiate U3 entry. An upstream port shall not reject U3 entry.

USB3PERI automatically responds to LGO\_U3, accepts it and transits to U3 state.

USB\_INT\_STA\_1.B3\_LNKCNG\_STA is asserted and an interrupt due to it is asserted if enabled.

PORTSC.PLS[3:0] shows U3 state (= 3h) after USB\_INT\_STA\_1.B3\_LNKCNG\_STA is asserted.

But only with the transition to U3 above, USB3.1 PHY is placed in P0 state or P2 state. If it is required to place PHY in P3 state, See the flow shown in **Section 34.6.5.8(1), Suspend in USB3.1 (Transition of State from U0 to U3)**.

**(k) In case downstream port requests the transition from U3 to U0**

When the downstream port wants to exit from U3 state and U3 Wakeup LFPS comes, USB3PERI automatically responds to it and returns to U0 state.

At that time, USB\_INT\_STA\_1.B3\_LNKCNG\_STA is asserted and an interrupt due to it is asserted if enabled.

PORTSC.PLS[3:0] shows U0 (= 0h) after USB\_INT\_STA\_1.B3\_LNKCNG\_STA is asserted.

**(l) In case device requests the transition from U3 to U0**

USB3PERI automatically requests the transition from U3 state to U0 by sending U3 Wakeup LFPS when the transition is requested on PORTSC.PLS[3:0]. In U3, PORTSC.PLS[3:0] shows U3 state (= 3h). If

PORTSC.PLS[3:0] is changed to U0 state (= 0h), USB3PERI sends U3 Wakeup LFPS to the link partner in order to request the transition from U3 state to U0 state.

When the LFPS handshake is completed and the link goes back to U0 state, USB\_INT\_STA\_1.B3\_LNKCNG\_STA is asserted and an interrupt due to it is asserted if enabled. PORTSC.PLS[3:0] shows U0 state (= 0h) after USB\_INT\_STA\_1.B3\_LNKCNG\_STA is asserted. See **Section 34.6.5.8(3), Resume in USB3.1 (from U3 to U0: Initiated by Device)** for details.

### (3) USB2.0 Power Control

In the specification of USB2.0 link power management, L0 state is defined as “On” state.

L3 state is defined as “Off” state and corresponds to the powered-off, disconnected and disabled state.

L2 state is defined as “Suspend” state and corresponds to so-called “USB2.0 suspend” in the past.

L1 state is defined as “Sleep” state. LPM transaction is defined for the state.

Table 34.6-65 USB2.0 Power Management

| State         | Configured (CONF)       | PLL Operation | CLK Gating |         |         |          | Supplement                                    |
|---------------|-------------------------|---------------|------------|---------|---------|----------|-----------------------------------------------|
|               |                         |               | CLK60      | CLK60_G | CLK60_P | CLK60_PG |                                               |
| L3            | —                       | Running       | Running    | Stopped | Stopped | Stopped  | (default)                                     |
|               |                         | Stopped       | Stopped    | Stopped | Stopped | Stopped  | PLL stop is requested on USB20_CON.B2_SUSPEND |
| L0            | Unconfigured (CONF = 0) | Running       | Running    | Running | Stopped | Stopped  | Only PIPE0 is running                         |
| L1/L2         | Configured (CONF = 1)   | Running       | Running    | Running | Running | Running  | All PIPEs are running                         |
|               |                         | Running       | Running    | Stopped | Running | Stopped  | (default)                                     |
| L1/L2<br>→ L0 |                         | Stopped       | Stopped    | Stopped | Stopped | Stopped  | PLL stop is requested on USB20_CON.B2_SUSPEND |
|               |                         | Running       | Running    | Running | Running | Running  | Wakeup received from Host                     |
|               |                         | Running       | Running    | Running | Running | Running  | Remote wakeup initiated by device             |

**Note:** CLK60 is a main clock used for USB2.0 related logic.

CLK60P is a generated clock from CLK60, and used for PIPEs other than PIPE0.

CLK60\_G and CLK60\_PG are generated clock from CLK60 and CLK60\_P, respectively.

#### [L3 (Off) State]

- Disconnected state for USB2.0
- PLL is running in default setting but it can be stopped on USB20\_CON.B2\_SUSPEND.
- 60MHz clock other than CLK60 is suspended.

#### [L0 (On) State]

- Active state in USB2.0 connection
- PLL is running.
- In unconfigured state, CLK60\_P and CLK60\_PG are suspended. It means that clock to PIPEs other than PIPE0 is suspended.
- In configured state, all clocks of 60MHz is running.

#### [L1 (Sleep) State]

- Low power state selected on LPM in USB2.0 connection
- PLL is running.
- CLK60\_G and CLK60\_PG are suspended.

**[L2 (Suspend) State]**

- Suspended state in USB2.0 connection
- PLL is running but it can be stopped on USB20\_CON.B2\_SUSPEND.  
PLL is resumed automatically when the wakeup request from downstream port is received.
- CLK60\_G and CLK60\_PG are suspended.

**(a) Transition from L0 to L1**

L1 state in USB2.0 is similar to U1 state and U2 state in USB3.1 in the point that the hardware should control the transition to or the exit from the state mainly. But unlike the transition to U1 state or U2 state, the transition to L1 state is initiated only by a downstream port.

LPM token is defined as one of an extended token packet for the transition. The device returns ACK if it accepts the transition or NYET if it rejects the transition when LPM token comes. It is also allowed to return STALL if it does not support LPM functions.

USB3PERI can respond with “no response” or return STALL to LPM token with the setting to do so, but it should return only ACK or NYET basically.

When LPM token from the downstream port comes, USB3PERI decides whether it accepts or not depending on the setting in the registers and the internal status.

LPM functions can be enabled or disabled on USB20\_CON.LPM\_DISABLE. When USB20\_CON.LPM\_DISABLE = 1, USB3PERI disables LPM functions and return no response to LPM token and take no action for it. But the device should support LPM functions, so it should enable LPM functions.

USB20\_CON.LPM\_ENABLE[1:0] also defines the response of USB3PERI to LPM token. If USB20\_CON.LPM\_ENABLE[1:0] = 10b (forced rejected), the request is rejected and USB3PERI returns NYET to LPM token. If USB20\_CON.LPM\_ENABLE[1:0] = 01b (forced accepted), the request is accepted and USB3PERI returns ACK to LPM token. If USB20\_CON.LPM\_ENABLE[1:0] = 00b (basically accepted), it depends on the internal status of USB3PERI whether it accepts the request or not. If USB20\_CON.LPM\_ENABLE[1:0] = 11b (unsupported), USB3PERI returns STALL to LPM token. But the device should not return STALL if it supports LPM functions.

If one of the conditions below is satisfied, the request is rejected and USB3PERI returns NYET. Otherwise, it is accepted and USB3PERI returns ACK.

- IN PIPE has one or more packets to be transmitted in buffer.

Figure 34.6-9 The Decision Flow Whether the Transition Request to L1 is Accepted or Not

The software can know that the transition to L1 state is requested on USB\_INT\_STA\_1.B2\_L1SPND\_STA. An interrupt due to it is asserted if enabled.

**(b) In case downstream port requests the transition from L1 to L0**

When the downstream port wants to exit from L1 state and the resume signal comes, USB3PERI automatically responds to it and returns to L0 state.

At that time, USB\_INT\_STA\_1.B2\_L1RSUM\_STA is asserted and an interrupt due to it is asserted if enabled.

**(c) In case device requests the transition from L1 to L0**

USB3PERI automatically requests the exit from L1 state to the downstream port by sending the resume signal when it has one or more packets to be transmitted in buffer for IN PIPE. In this case, there is no additional operation to exit from L1 state.

The transition from L1 state to L0 state is also required by setting USB20\_CON.B2\_RSUM\_IN. When this bit is set, the resume signal to request the exit from L1 state is sent to the downstream port.

**(d) Transition from L0 to L2 (Suspend)**

L2 state is defined as USB2.0 Suspend in the original USB2.0 specification. The transition to L2 state is requested only from downstream port and is controlled automatically by the hardware of USB3PERI.

The downstream port can request the transition to L2 state by stopping any bus activity and put USB bus in a constant idle state for more than 3.0 ms and device cannot deny the transition.

When USB3PERI detects that the transition to L2 state is being requested from downstream port (that is, USB bus stays in idle state for more than 3.0 ms), it automatically follows it and asserts USB\_INT\_STA\_1.B2\_SPND\_STA.

USB3PERI follows to the request of the transition to L2 state, but PLL in USB2.0-PHY is still running in L2 state. If it is required to stop PLL, set USB20\_CON.B2\_SUSPEND. See **Section 34.6.5.8(7), Suspend in USB2.0** for details.

**(e) In case downstream port requests the transition from L2 to L0**

When the downstream port wants to exit from L2 state and the resume signal comes, USB3PERI automatically responds to it and returns to L0 state.

At that time, USB\_INT\_STA\_1.B2\_RSUM\_STA is asserted and an interrupt due to it is asserted if enabled.

**(f) In case device requests the transition from L2 to L0**

The software can requests the wakeup of USB3PERI from L2 state. If PLL in USB2.0-PHY is suspended, it should be awoken first. See **Section 34.6.5.8(10), USB2.0 PHY (PLL) Wakeup Process** for how to awake PLL in USB2.0-PHY.

After PLL is resumed, the software can send the resume signal from USB3PERI by setting USB20\_CON.RSUM\_IN. See **Section 34.6.5.8(9), Resume in USB2.0 (Initiated by Device)** for details

#### 34.6.4.4 AXI DMA Transfer Control

USB3PERI executes DMA transfer to or from data buffers connected to SRAM interface using the bus master function of AXI-IF. The DMA master function of AXI-IF uses Physical Region Descriptor (PRD) Table on system memory, which has a source address, a destination address, a size of transfer and other information related to the DMA transfer. It is assumed that the software (driver, for example) prepares PRD table on system memory. PRD tables are prepared separately for each PIPE.

The operation flow of DMA transfer using master function of AXI-IF is described below.

##### (1) OUT Transfer

- (1) Interrupt is asserted if PRD table is not prepared

AXI-IF asserts AXI\_INT\_SYS if a certain PIPE receives OUT packet and the OUT packet becomes ready to be read but PRD table is not prepared for it yet.

If PRD table is already prepared for the PIPE and DMA transfer is enabled, AXI-IF does not assert AXI\_INT\_SYS here. In that case, (2) and (3) can be skipped.

- (2) Making PRD table

The software makes PRD table according to the defined format.

- (3) Setting for bus master

The software specifies PRD table made at (2) to registers of AXI-IF, and enables DMA transfer.

- (4) Start of DMA transfer

AXI-IF reads PRD table when it detects EPC\_D\_Pn\_DATAEN[n] (n is the index of the PIPE for which PRD table is prepared for) is asserted and knows EPC requests DMA transfer. Then, AXI-IF writes received data in a unit of packet to the address which is assigned by PRD table.

- (5) Writing back the result of transfer to PRD table

When DMA transfer is completed, AXI-IF writes back the result of transfer to PRD table.

- (6) Interrupt is asserted to notify completion of DMA transfer

AXI-IF asserts AXI\_INT\_DMA when it completes DMA transfer.

Figure 34.6-10 Example of Operation for OUT Transfer

**(2) IN Transfer**

- (1) Interrupt asserted if PRD table is not prepared

AXI-IF asserts AXI\_INT\_SYS if a certain PIPE becomes ready to be written for IN packet but PRD table is not prepared for it yet.

If PRD table is already prepared for the PIPE and DMA transfer is enabled, AXI-IF does not assert an interrupt. In that case, (2) and (3) can be skipped.

- (2) Making PRD table

The software makes PRD table according to the defined format.

- (3) Setting for bus master

The software specifies PRD table made at (2) to registers of AXI-IF, and enables DMA transfer.

- (4) Start of DMA transfer

AXI-IF reads PRD table when it detects EPC\_D\_Pn\_DATAEN[n] (n is the index of the PIPE for which PRD table is prepared for) is asserted and knows EPC requests DMA transfer. Then, AXI-IF read data to be transmitted in unit of a packet from the address which is assigned by PRD table.

- (5) Write back of result of transfer to PRD table

When DMA transfer is completed, AXI-IF writes back the result of transfer to PRD table.

- (6) Interrupt asserted to notify completion of DMA transfer

AXI-IF asserts AXI\_INT\_DMA when it completes DMA transfer.

Figure 34.6-11 Example of Operation for IN Transfer

### (3) Two PRD Tables for One Group of Transfer

The basic concept of two PRD tables used for one group of transfer is described below. Especially the Stream bulk protocol is assumed here.

For Stream bulk transfer, Stream ID is assigned to USB3PERI and it executes transfer related to the Stream ID. The Stream ID is set before PRD table is allocated to USB3PERI.

From the viewpoint of the performance of system, it is desirable to prepare for the next transfer just before the current OUT transfer is completed. USB3PERI can execute transfer seamlessly in that case.

In order to do so, there is a way to use PRD tables for one group of transfer.

Two PRD tables are prepared so that the group of transfer is divided to them beforehand. One PRD table has the part from the first packet to the (n)-th packet, and the other table has that from the (n+1) th packet to the last packet. The (n) is assumed as the second or the third packet from the last. The Int bits are set for both tables. With this usage, the software can know the current transfer is almost completed by the interrupt of the first PRD table. When the interrupt of the first PRD table comes, software can start the preparation for the next transfer. It can also confirm the completion of the current transfer by the interrupt of the second PRD table.

This method is applicable for non Stream bulk transfer.

Figure 34.6-12 Two PRD Tables Used for One Group Transfer

#### (4) DMA Transfer using EXTPRD\_EN

AXI-IF has four register groups used for DMA transfers, -- DMA\_Ch0\_CONx and DMA\_Ch0\_PRD\_ADRx (x = 1-4). AXI-IF can coordinate multiple PRD tables and their transfers by making links between those PRD tables on DMA\_Ch0\_CONx.EXPRD\_ENx and DMA\_Ch0\_CONx.EXTPRD\_NOx[1:0].

An example in case that multiple PRD tables and their transfers are coordinated on DMA\_Ch0\_CONx.EXPRD\_ENx is described below. In this example, PRD tables from (1) to (4) are set to registers at first, and then PRD table of (5) is set after DMA transfer of (1) is completed. Since DMA\_Ch0\_CONx.EXPRD\_ENx is set to 1 for (2), (3) and (5), each DMA\_Ch0\_CONx.PRД\_ENx is masked and each DMA transfer is kept waiting until the transfer related on DMA\_Ch0\_CONx.EXTPRD\_NOx[1:0] is completed.

As for (2), DMA\_Ch0\_CON2.EXTPRD\_NO2[1:0] = 0 is specified. In this case, the transfer related to (2) is suspended until the transfer at PIPE1 with DMA\_Ch0\_CON1 is completed. When the transfer at PIPE1 with DMA\_Ch0\_CON1 is completed and DMA\_Ch0\_CON1.PRД\_EN1 is cleared by hardware, DMA\_Ch0\_CON2.EXTPRD\_EN2 is cleared automatically by hardware at the same time. The clearing of DMA\_Ch0\_CON2.EXTPRD\_EN2 means that DMA\_Ch0\_CON2.PRД\_EN2 gets unmasked, and the transfer of (2) is allowed at this point.

[Example of PRD Table Setting]

| No. |              | PRD_EN | PIPE_NO | EXTPRD_EN    | EXTPRD_NO |
|-----|--------------|--------|---------|--------------|-----------|
| (1) | DMA_Ch0_CON1 | 1      | PIPE1   | 0 (Normal)   | —         |
| (2) | DMA_Ch0_CON2 | 1      | PIPE1   | 1 (Expanded) | 0 (CON1)  |
| (3) | DMA_Ch0_CON3 | 1      | PIPE2   | 1 (Expanded) | 1 (CON2)  |
| (4) | DMA_Ch0_CON4 | 1      | PIPE3   | 0 (Normal)   | —         |
| (5) | DMA_Ch0_CON1 | 1      | PIPE1   | 1 (Expanded) | 2 (CON3)  |

[Example of Operation]

Figure 34.6-13 Transfer Using EXTPRD\_EN

This function is also used for the case a certain PIPE is expected to start the transfer just after that at other PIPE is completed.

DMA\_Ch0\_CONx.EXTPRD\_NOx[1:0] and DMA\_Ch0\_CONx.EXTPRD\_ENx should be set before the transfer for PRD table related on DMA\_Ch0\_CONx.EXTPRD\_NOx[1:0] is completed (when it is completed, DMA\_Ch0\_CONx.PRД\_ENx is cleared). Make sure that DMA\_Ch0\_CONx.PRД\_ENx is still 1 just when DMA\_Ch0\_CONx.EXTPRD\_NOx[1:0] and DMA\_Ch0\_CONx.EXTPRD\_ENx are set and related to it. If DMA\_Ch0\_CONx.PRД\_ENx has already been cleared, do not use DMA\_Ch0\_CONx.EXTPRD\_NOx[1:0] and DMA\_Ch0\_CONx.EXTPRD\_ENx for it.

#### (5) Example of transfer using bus master function

An Example in which short packet is received as the last one at OUT (AXI write) PIPE is described below.

AXI-IF provides 4 register groups to have the information of PRD Tables. The software prepares PRD Table on system memory and requests the transfer by setting the start address of PRD table, the information of PIPE (index of PIPE and direction of transfer) and DMA\_Ch0\_CONx.PRД\_ENx to one of register groups. Especially setting of DMA\_Ch0\_CONx.PRД\_ENx to 1 means the transfer on the PIPE is enabled.

EPC indicates whether transfer is enabled or not for each PIPE on EPC\_D\_Pn\_DATAEN[n] (n = 1-15), which is one of the signals at Data Interface of EPC.

AXI-IF is kept waiting until EPC notifies it that the transfer of PIPE related on the PRD table is enabled. AXI-IF starts the transfer when it detects that one of transfers related on PRD tables is enabled.

Upon the start of transfer, AXI-IF reads the first PRD table. When the type of PRD table is a link pointer, AXI-IF executes writing-back in order to set used bit of the PRD table first and then reads the next PRD table from the address which is held in BAP. When the type of PRD table is a buffer pointer, AXI-IF starts data transfer according to the PRD table.

EPC executes data transfer at Data Interface in a unit of a packet of USB (the size of packet is up to the max packet size of USB).

When the transfer of the packet is completed, AXI-IF updates the PRD table that was read just prior to the transfer and writes back it so that SIZE field and BAP field in the table are updated. If the remain size of the PRD table is not zero and EPC notifies AXI-IF that it can still continue transfer of the PIPE when AXI-IF completes writing-back of PRD table, AXI-IF uses PRD table currently held and start transfer of the next packet for the PIPE. On the contrary, in case that all transfers specified by the PRD table held currently in AXI-IF have been done, case that the transfer for the PRD table is terminated by receiving short packet or case that EPC notifies that no transfer on the PIPE is pending, AXI-IF returns back to the status to wait for transfer.

When the transfer is completed, the size information in SIZE field of table is updated to the value that the size of transferred packet is subtracted from the remaining size before the transfer, then AXI-IF writes back the PRD table.

If it is required to know the actual size transferred, store the remaining size before the transfer, and subtract the size in the updated PRD table after the transfer from it.

In case that short packet is received in the middle of PRD Table or case that all transfers specified by PRD table have been completed, AXI-IF completes the process of the current PRD table. At this time AXI-IF clears DMA\_Ch0\_CONx.PRД\_ENx, sets the status bit in DMA\_INT\_STA register and asserts AXI\_INT\_DMA if enabled.

Figure 34.6-14 Example of OUT Transfer Terminated with Short Packet

## (6) Finishing the Process for PRD Table and Its Conditions

AXI-IF has DMA\_Ch0\_CONx and DMA\_Ch0\_PRD\_ADRx (x = 1-4) to have the information of PRD tables, and starts transfer when it detects EPC\_D\_Pn\_DATAEN[n] (n = 1-15) at Data Interface is asserted from EPC. Asserting EPC\_D\_Pn\_DATAEN[n] indicates that transfer on PIPE specified in one of register groups is enabled. Transfer is executed in a unit of a packet of USB (that is, the size is up to the max packet size of USB), following the order specified by PRD tables. When one of the conditions to finish the transfer is satisfied, AXI-IF recognizes that the process of the current PRD table has been completed, clears DMA\_Ch0\_CONx.PRD\_ENx and sets the interrupt status in DMA\_INT\_STA register. AXI-IF finishes the transfer of PRD table when one of the conditions below is satisfied.

- (1) All transfers related from the first PRD table to the last one (End bit is set) have been completed, or
- (2) Transfer is terminated by receiving short packet in OUT transfer (AXI write transfer), or
- (3) EPC\_D\_DBRTRANSEND which indicates the end of transfer is asserted in OUT transfer (AXI Write transfer), or
- (4) PRD\_Table is incorrect, or
- (5) EPC requests ABORT during transfer on Data-IF.  
(EPC never requests ABORT as far as the operation of the software is compliant to the flow in this manual.)

The following cases are the conditions of abnormal termination of transfer due to error. But they are avoidable by the configuration of system and assumed that they never occur in the normal usage. Make sure to configure the system so that those errors never occur.

- (6) An error occurs in read process of PRD table, or
- (7) An error response is received during data transfer on AXI, or
- (8) An error occurs in writing-back of PRD Table.

In cases of (2) and (3) transfer is terminated in the middle of PRD tables. In these cases, used bit in the PRD table of the completed transfer is set. Besides, if the amount of transferred data is less than the size specified in PRD table, the size

field of the PRD table is changed to the remaining amount of data after the transfer has been terminated. The actual amount of transferred data can be calculated by subtracting the remaining amount of data from the size specified in PRD table initially.

The case of (5) occurs when clearing buffers of EPC is requested on Pn\_CON.Pn\_BCLR or P0\_CON.P0\_BCLR during transfer is being executed at Data interface. But since it is not recommended in this manual, the case of (5) is assumed to never occur as long as the software is compliant to the flow. When the case occurs, used bit and Data Error bit in the PRD table for which the transfer is being executed are set to 1 and AXI\_INT\_STA.PRDERRO\_x\_STA is asserted.

The cases of (6) and (8) mean that read or write specified by PRD Table could not be executed. In those cases, AXI\_INT\_STA.PRDERRO\_x\_STA is asserted.

For the case of (7), as far as (8) does not occur concurrently, used bit and Data Error bit in PRD table are set to 1 and AXI\_INT\_STA.PRDERRO\_x\_STA is asserted similarly to (5).

But in case (8) occurs at the same time, it means that writing-back of PRD table fails and the result of transfer is not stored in PRD table. AXI-IF terminates the transfer at Data Interface with EPC.

It is assumed in the design of USB3PERI that it would not receive an error response on AXI-bus. Make sure to configure the system not to return an error response on AXI bus to USB3PERI.

### **(7) Case of Error**

There are two kinds of errors in USB3PERI. One is an error due to the mistake in the setting and the other is the transfer error caused by receiving an error response on AXI bus.

But USB3PERI was designed on the premise that it would not receive an error response (for both of read and write) on AXI bus when it executes DMA transfer, so USB3PERI only reports that the transfer error occurs for debug use. Make sure to configure system so that it does not return an error response on AXI bus to USB3PERI.

In case an error occurs at AXI-IF, AXI-IF automatically clears DMA\_Ch0\_CONx.PRD\_ENx for the current PRD table so that the current transfer is terminated, and asserts AXI\_INT\_STA.PRDERRO\_x\_STA at the same time.

In case an error occurs at AXI-IF, the result of the current transfer is not guaranteed. Make sure not to use transferred data when the error occurs.

### **(8) Ordering of Transactions**

USB3PERI operates AXI transactions in order. Hence USB3PERI always uses the same value “0h” as MAWID[3:0], MWID[3:0] and MARID[3:0].

(9) Write Transfer with All Zero Strobe

USB3PERI can execute two outstanding transactions and issues two outstanding addresses on AXI address channel checking the max packet size and the rest of buffer assigned by PRD table.

But, in OUT transfer (which requires the write transfer on AXI bus), the received packet might be the short one and its size might be less than both of the max packet size and the rest of buffer. In that case, USB3PERI might have no more data to be transferred although it has already issued the transfer address on AXI write address channel. For that case, USB3PERI executes the write transfer with all zero strobe on MWSTRB[7:0] so that no write occurs at target.

**Figure 34.6-15** shows the case that USB3PERI receives the short packet and it has data to transferred for ADR1 but does not for ADR2. Then, USB3PERI executes the write transfer with all zero strobe on MWSTRB[7:0] for ADR2.

In **Figure 34.6-15** the write transfer with all zero strobe starts from the head of the transfer, but MWSTRB[7:0] might be set to all zero in the middle of transfer depending on the size of the received packet.

Therefore USB3PERI requires the target on AXI bus to accept the write transfer with all zero strobe and discard the write data for the transfer.

Figure 34.6-15 Write Transfer with All Zero Strobe

**(10) Interrupts**

Pn\_DMACNG\_STA(n = 1-15) in DMA\_INT\_STA is asserted in the cases below.

1. PRD\_ENx in DMA\_Ch0\_CONx(x = 1-4) assigned for PIPE n is cleared due to the completion of transfer (completion of transfer means that Lst bit in PRD table is set and data assigned to it has been transferred, the short packet has been received for OUT PIPE, PP bit is cleared in received USB3.1 data packet with non ZLP mode or that an error has occurred in transfer).
2. PIPE which is not assigned to DMA\_Ch0\_CONx becomes ready (It can accept the next packet for IN transfer, or it has new received packet for OUT transfer).
3. Transfer of descriptor in which Int bit is set is completed.

Especially Pn\_DMACNG\_STA is asserted in case 2 as follows.

When PIPE n is IN pipe and DMA\_Ch0\_CON1 (for example) is assigned for the DMA transfer with it, Pn\_DMACNG\_STA is asserted at the completion of DMA transfer. If multiple pipes are enabled, DMA\_Ch0\_CON1 is assigned to another PIPE (PIPE m in this example) as soon as DMA transfer with PIPE n is completed. But the transmission of packets has not been completed at PIPEn. Pn\_DMACNG\_STA is asserted again when no DMA\_Ch0\_CONx is assigned to PIPE n and it has transmitted the last packet.

Figure 34.6-16 The Behavior of Pn\_DMACNG\_STA in IN Transfer

When PIPE n is OUT pipe but no DMA\_Ch0\_CONx is assigned to it, Pn\_DMACNG\_STA is asserted every time PIPEn receives a packet.

Figure 34.6-17 The Behavior of Pn\_DMACNG\_STA in OUT Transfer

Note that Pn\_DMACNG\_STA is not asserted if DMA\_Ch0\_CONx is assigned when the last IN packet has been transmitted or when the OUT packet has been received.

As noted above, Pn\_DMACNG\_STA might be asserted due to the causes except for DMA transfer. When it is required to know only the completion of DMA transfer, see PRD\_ENx\_CLR\_STA in AXI\_INT\_STA instead.

### 34.6.4.5 List of Interrupt Factors

The interrupt factors for USB3PERI/EPC are shown below.

Figure 34.6-18 The System Diagram for the Interrupt

Table 34.6-66 Interrupt Factors at AXI-IF: AXI\_INT\_STA Register

| Interrupt Factors | Descriptions                                                                         |
|-------------------|--------------------------------------------------------------------------------------|
| DMAINT_STA        | This factor shows the status of the interrupt by DMA transfer.                       |
| EPCINT_STA        | This factor shows the status of the interrupt of EPC_INTR_USB.                       |
| PRDEN4_CLR_STA    | This factor indicates that DMA_CH0_CON4.PRD_EN4 has been cleared by hardware.        |
| PRDEN3_CLR_STA    | This factor indicates that DMA_CH0_CON3.PRD_EN3 has been cleared by hardware.        |
| PRDEN2_CLR_STA    | This factor indicates that DMA_CH0_CON2.PRD_EN2 has been cleared by hardware.        |
| PRDEN1_CLR_STA    | This factor indicates that DMA_CH0_CON1.PRD_EN1 has been cleared by hardware.        |
| PRDERR0_4_STA     | This factor indicates that there was an error in PRD table assigned to DMA_CH0_CON4. |
| PRDERR0_3_STA     | This factor indicates that there was an error in PRD table assigned to DMA_CH0_CON3. |
| PRDERR0_2_STA     | This factor indicates that there was an error in PRD table assigned to DMA_CH0_CON2. |
| PRDERR0_1_STA     | This factor indicates that there was an error in PRD table assigned to DMA_CH0_CON1. |

Table 34.6-67 Interrupt Factors at AXI-IF: DMA\_INT\_STA Register

| Interrupt Factors  | Descriptions                                                                  |
|--------------------|-------------------------------------------------------------------------------|
| P[15-1]_DMACNG_STA | This factor shows the status of the interrupt by DMA transfer for PIPE[15-1]. |

Table 34.6-68 Interrupt Factors at AXI-IF: USB\_INT\_STA\_1 Register

| Interrupt Factors | Descriptions                                                                                                                                                                                                                                                                                     |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| B3_PLLWKUP_STA    | This factor indicates that PHY30_CLK125_IN was resumed due to PLL wakeup (USB30_CON.B3_PLLWAKE was set or the input signal B3_PLL_WAKEIN is asserted) or U3 Wakeup LFPS from host.                                                                                                               |
| B3_LUPSUCS_STA    | This factor indicates that the link of USB3.1 has been established (LTSSM enters U0 state from Polling state).                                                                                                                                                                                   |
| B3_POLLING_STA    | This factor indicates that LTSSM has made the transition to Polling state.                                                                                                                                                                                                                       |
| B3_INACTV_STA     | This factor indicates that LTSSM has made the transition to Inactive state.                                                                                                                                                                                                                      |
| B3_DISABLE_STA    | This factor indicates that LTSSM has made the transition to Disabled state.                                                                                                                                                                                                                      |
| B3_VNDTST_STA     | This factor indicates that Vendor Device Test LMP has been received.                                                                                                                                                                                                                             |
| B3_U2INACT_STA    | This factor indicates that U2 Inactivity Timeout LMP has been received.                                                                                                                                                                                                                          |
| B3_SETLNK_STA     | This factor indicates that Set Link Function LMP has been received.                                                                                                                                                                                                                              |
| B3_LNKCNG_STA     | This factor indicates that LTSSM has made the transition as listed below.<br>U0 -> U1<br>U0 -> U2<br>U0 -> U3<br>U3 -> Recovery -> U0<br>U2 -> Recovery -> U0<br>U1 -> Recovery -> U0                                                                                                            |
| B3_WMRST_STA      | This factor indicates that warm reset has been received.                                                                                                                                                                                                                                         |
| B3_HOTRST_STA     | This factor indicates that hot reset has been received.                                                                                                                                                                                                                                          |
| B3_PSFAIL_STA     | This factor indicates that the transition of POWERDOWN mode on USB30_CON.POW_SEL[2:0] failed.                                                                                                                                                                                                    |
| B3_PSSUCS_STA     | This factor indicates that the transition of POWERDOWN mode on USB30_CON.POW_SEL[2:0] has been completed successfully.                                                                                                                                                                           |
| B3_U12REQ_STA     | This factor indicates that USB3PERI received LGO_U1/U2 or when U1/U2_TIMER in SSIF was expired.                                                                                                                                                                                                  |
| B3_TPSUCS_STA     | This factor indicates that TP (Device Notification) requested on USB30_CON.B3_TP_SEND has been successfully completed.                                                                                                                                                                           |
| B2_LPMRCV_STA     | This factor indicates that USB3PERI has received LPM request from USB2.0 host and has returned ACK to it.                                                                                                                                                                                        |
| B2_USBRST_STA     | This factor indicates that USB2.0 bus reset has been received.                                                                                                                                                                                                                                   |
| B2_L1SPND_STA     | This factor indicates that L1 suspend request has been received from USB2.0 host.                                                                                                                                                                                                                |
| B2_L1RSUM_STA     | This factor indicates that PLL wakeup has been requested (USB20_CON.B2_SUSPEND = 0 or B2_PLL_WAKEIN = 1) or when the resume request from USB2.0 host has been received (USB_STA.B2_L1RSUM_OUT changes from 0 to 1) during L1 state (USB_STA.B2_L1_SPND_OUT = 1).                                 |
| B2_SPND_STA       | This factor indicates that the suspend request has been received from USB2.0 host and USB_STA.B2_SPND_OUT changes from 0 to 1.                                                                                                                                                                   |
| B2_RSUM_STA       | This factor indicates that PLL wakeup has been requested (USB20_CON.B2_SUSPEND = 0 or B2_PLL_WAKEIN=1) or when the resume request from USB2.0 host has been received (USB_STA.B2_RSUM_OUT changes from 0 to 1) during L2 state (USB_STA.B2_SPND_OUT = 1) or L3 state (USB20_CON.B2_CONNECT = 0). |
| SPEED_STA         | This factor indicates that there was a change in the speed mode of USB.                                                                                                                                                                                                                          |
| VBUS_CNG_STA      | This factor indicates that the level of the input signal "VBUS" was changed.                                                                                                                                                                                                                     |

Table 34.6-69 Interrupt Factors at AXI-IF: USB\_INT\_STA\_2 Register

| Interrupt Factors  | Descriptions                                                            |
|--------------------|-------------------------------------------------------------------------|
| PIPE[15:0]_INT_STA | This factor indicates that an interrupt related to PIPE[15:0] occurred. |

Table 34.6-70 Interrupt Factors at AXI-IF: P0\_INT\_STA Register

| Interrupt Factors | Descriptions                                                                                                                                                                                                                      |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| P0_STSED_STA      | This factor indicates that status stage of control transfer has been completed successfully.                                                                                                                                      |
| P0_STSST_STA      | This factor indicates that status stage of control transfer has been started at PIPE0.                                                                                                                                            |
| P0_SETUP_STA      | This factor indicates that valid setup data has been received at PIPE0.                                                                                                                                                           |
| P0_RCVNL_STA      | This factor indicates that null data has been received at PIPE0.                                                                                                                                                                  |
| P0_ERDY_STA       | This factor indicates that the condition to send ERDY was satisfied at PIPE0.                                                                                                                                                     |
| P0_FLOW_STA       | This factor indicates that PIPE0 has entered flow control state.                                                                                                                                                                  |
| P0_STALL_STA      | This factor indicates that STALL has been sent at PIPE0.                                                                                                                                                                          |
| P0_NRDY_STA       | This factor indicates that NRDY or NAK has been sent at PIPE0.                                                                                                                                                                    |
| P0_BFRDY_STA      | In case the direction of transfer is IN (P0_MOD.P0_DIR = 1), the next data can be written to P0_WRITE register.<br>In case the direction of transfer is OUT (P0_MOD.P0_DIR = 0), the next data can be read from P0_READ register. |

Table 34.6-71 Interrupt Factors at AXI-IF: Pn\_INT\_STA Factors

| Interrupt Factors | Descriptions                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pn_CBW_STA        | This factor indicates that CBW has been received at PIPEn and is ready to be read from Pn_READ register.                                                                                                                                                                                                                                                                                                                                     |
| Pn_STERR_STA      | This factor indicates that Stream bulk protocol error has occurred at PIPEn.                                                                                                                                                                                                                                                                                                                                                                 |
| Pn_STRMX_STA      | This factor indicates that Stream ID in received packet was different from that in Pn_STREAM.Pn_STREAM_C.                                                                                                                                                                                                                                                                                                                                    |
| Pn_NSTRM_STA      | In case the direction of transfer is IN (Pn_MOD.Pn_DIR = 1), this factor indicates that ACK_TP(NoStream) has been received at PIPEn.<br>In case the direction of transfer is OUT (Pn_MOD.Pn_DIR = 0), this factor indicates that DP(NoStream) has been received at PIPEn.                                                                                                                                                                    |
| Pn_PRIME_STA      | In case the direction of transfer is IN (Pn_MOD.Pn_DIR = 1), this factor indicates that ACK_TP(PRIME) has been received at PIPEn.<br>In case the direction of transfer is OUT (Pn_MOD.Pn_DIR = 0), this factor indicates that DP(PRIME) has been received at PIPEn.                                                                                                                                                                          |
| Pn_RCVNL_STA      | This factor indicates that zero length packet has been received at PIPEn.                                                                                                                                                                                                                                                                                                                                                                    |
| Pn_ERDY_STA       | This factor indicates that the condition to send ERDY has been satisfied at PIPEn.                                                                                                                                                                                                                                                                                                                                                           |
| Pn_FLOW_STA       | This factor indicates that PIPEn has entered flow control state.                                                                                                                                                                                                                                                                                                                                                                             |
| Pn_LSTTR_STA      | In case the direction of transfer is IN (Pn_MOD.Pn_DIR = 1), this factor indicates that the last data of the transfer (short packet, packet for which Pn_LAST was set or packet for which EPC_D_DBWTRANSEND was asserted) has been sent at PIPEn.<br>In case the direction of transfer is OUT (Pn_MOD.Pn_DIR = 0), this factor indicates that the last data of the transfer (short packet or packet with PP = 0) has been received at PIPEn. |
| Pn_STALL_STA      | This factor indicates that STALL has been sent at PIPEn.                                                                                                                                                                                                                                                                                                                                                                                     |
| Pn_NRDY_STA       | This factor indicates that NRDY or NAK has been sent at PIPEn.                                                                                                                                                                                                                                                                                                                                                                               |
| Pn_BFRDY_STA      | In case the direction of transfer is IN (Pn_MOD.Pn_DIR = 1), the next data can be written to Pn_WRITE register.<br>In case the direction of transfer is OUT (Pn_MOD.Pn_DIR = 0), the next data can be read from Pn_READ register.                                                                                                                                                                                                            |

### 34.6.4.6 Zero Length Packet (ZLP)

#### (1) Definition of Zero Length Packet

Zero length packet (ZLP) is the data packet (DP) but it has no data word in its data payload. ZLP is used to show the boundary of the transfer in some USB device classes, in case that the size of the last data packet equals to the max packet size of the PIPE.

Short packet, which length of data is less than the max packet size of the PIPE, is interpreted as the last packet of transfer in general. For example, it is defined that the size of packet except the last one in bulk transfer should be the max packet size of the PIPE. But it differs how to treat the case that the size of the last packet of transfer equals to the max packet size of the PIPE, depending on USB device class.

It is difficult to know whether the received packet which has the length same as the max packet size is the last one or not for the receiver (host or device). In some USB device classes, ZLP is sent next to show that there is the boundary of transfer. But in Bulk Only Transfer (BOT), ZLP is not used because CBW notifies the amount of transfer in advance. The device might transmit data less than the amount shown in CBW and the size of the last data packet might be the max packet size, but CSW is transferred next even in that case and CSW of 13 bytes is the short packet in bulk transfer. Therefore host can know that the packet just before CSW was the last data packet. In Stream bulk transfer, the packet with PP = 0 to show the end of transfer related the current Stream ID.

See the specification of USB device class to know whether ZLP is really required or not.

#### (2) Transfer of ZLP Support Mode in USB3PERI

USB3PERI has the mode to support ZLP transfer. Set USB\_COM\_CON.Pn\_WDATAIF\_NL, USB\_COM\_CON.Pn\_RDATAIF\_NL and USB\_COM\_CON.Pn\_LSTTR\_PP to 1 in order to use the mode.

### (3) In the Configuration with AXI-IF

USB3PERI sends ZLP for OUT transfer and receives ZLP for IN transfer automatically with the settings for them. In order to transmit ZLP in ZLP transfer, the software sets ZL bit in PRD table where ZLP is requested to be transmitted in advance. When USB3PERI receives ZLP in OUT transfer, it sets ZL bit in PRD table where ZLP is received.

USB\_COM\_CON.Pn\_WDATAIF\_NL, USB\_COM\_CON.Pn\_RDATAIF\_NL and USB\_COM\_CON.Pn\_LSTTR\_PP should be set to 1 as noted in **Section 34.6.4.4(2), IN Transfer**.

For IN transfer, with PRD table in which Lst=1 and ZL=1, USB3PERI sends ZLP after the last data packet of the PRD table in order to show the boundary of transfer. With PRD table in which Lst = 0 or ZL = 0, USB3PERI never sends ZLP.

Therefore, set both of Lst bit and ZL bit to 1 in the PRD table which has the last data packet and requires ZLP after it. In other PRD tables, set both of Lst bit and ZL bit to 0.

Note that the meaning of 0000h in SIZE field of PRD table differs depending on ZL bit and Lst bit. If ZL = 1 and Lst = 1, 0000h in SIZE field means that 0 byte transfer is requested by the PRD table. Otherwise, 0000h means that 64 Kbytes transfer is requested.

If ZLP is required after 64 Kbytes data has been transferred, prepare two PRD tables. The first one has 64 Kbytes data (SIZE field is 0000h) with Lst = 0 and ZL = 0, and the second one has 0 bytes data (SIZE field is 0000h) with Lst=1 and ZL=1.

For OUT transfer, the software is never required to set Lst bit and ZL bit in PRD table. When USB3PERI receives ZLP in OUT transfer, it sets both of Lst bit and ZL bit to 1 in the PRD table. If USB3PERI has already received some packets before ZLP, USB3PERI transfers them to system memory where the PRD table designates, then it sets Lst bit and ZL bit in the PRD table.

If USB3PERI does not receive ZLP but short packet (which length is not 0), it sets Lst bit to 1 but leave ZL bit as 0.

Note that the meaning of 0000h in SIZE field of PRD table differs depending on ZL bit and Lst bit. If ZL=1 and Lst = 1, 0000h in SIZE field means that 0 byte data is contained in the buffer designated by the PRD table. Otherwise, 0000h means 64 Kbytes data is contained in the buffer.

If ZLP is received after 64-Kbyte data has been received, two PRD tables are used. The first one shows SIZE = 0000h, Lst=0 and ZL=0, and it means that 64-Kbyte data has been received but ZLP isn't included. The second one shows SIZE = 0000h, Lst=1 and ZL=1, and it means that only ZLP has been received for the PRD table.

### 34.6.5 Examples of software flow

#### 34.6.5.1 Outline of software flow

The software for USB3PERI is described in this section. The flow includes initialization, interrupt handling, control transfer process, bulk transfer process and interrupt transfer process.

Note that the flow described here is an example in general usage of USB3PERI. Modification of the flow or additional operation might be required depending on application in which user's system assumes.

The loop as below is used at some points in the flow and assumes the read polling of register by software. The interrupt notification might be used instead, but note that the setting to enable the interrupt is required in that case.

In order to access registers related to PIPEn, the index of PIPE should be set in PIPE\_COM.PIPE\_NUM[4:0] in advance. Note that the setting of the index of PIPE is omitted in each step of this section.

### 34.6.5.2 Initialization

The initialization should be completed before the device is used as USB device.

It is recommended that the initialization is done immediately after the power to device is turned on.

Figure 34.6-19 Initialization Flow

## (1) Set PHY control registers

Set PHY control registers if required.

When the software accesses to PHY control register, set AXI\_CON.PHY\_CTRL before the access.

1. AXI\_CON.PHY\_CTRL = 1
2. Access to PHY control register
3. AXI\_CON.PHY\_CTRL = 0

## (2) Set AXI-IF registers

The setting of AXI-Bridge is changed here if default values of the parameters for AXI-bus below are not consistent with the user's system.

- AXI\_CON.MST\_BSIZE[1:0] (Burst size setting: default value 8 bytes)
- AXI\_CON.MST\_ARPROT[2:0] (Read protection type: default value 010b)
- AXI\_CON.MST\_AWPROT[2:0] (Write protection type: default value 010b)

## (3) Set EPC registers

Set the operation mode and initialize the interrupt status in EPC as follows.

## a) USB30\_CON register

If U3\_POW\_SEL[1:0] is required to be changed from default settings, change them here.

## b) USB\_INT\_STA\_1 register

Write 1 to all status bits in USB\_INT\_STA\_1 in order to clear them.

## c) USB\_INT\_ENA\_1 register

Set VBUS\_CNG\_ENA to 1 in order to enable VBUS change interrupt.

It is also recommended to enable B3\_HOTRST\_ENA. See **Section 34.6.5.3(5), Hot Reset Process** for details.

## (4) Set SSIF registers

The setting of SSIF is changed here if required. But it is recommended to use them with default settings basically.

## (5) Check VBUS status

Check whether the status of USB\_STA.VBUS\_STA has already changed to 1 or not.

If USB\_STA.VBUS\_STA = 1, proceed to the operation of connection. See **Section 34.6.5.3(2), USB Connection**.

### 34.6.5.3 Interrupt Process

When an interrupt is asserted, see the interrupt status register to know what factor causes the interrupt, and then do the operation required.

Examples of the flow for interrupt are shown in this section.

#### (1) Interrupt Handler Process

The process in interrupt handler when an interrupt is asserted is described here.

Figure 34.6-20 Interrupt Handler Process Flow

#### (1) Check the interrupt factor

See interrupt status register to know what factor is the cause of the interrupt. Then clear the status bit in interrupt status register.

It is assumed here that the interrupt is asserted due to PIPEn event, so registers related to PIPEn are accessed later. If it is required to remember the interrupt factor in main process, prepare the variable to remember it.

#### (2) Read the current index of PIPE

The software should read the current index of PIPE and remember it before it changes the index of PIPE in PIPE\_COM.PIPE\_NUM[4:0] due to the interrupt asserted by PIPEn event and the succeeding operation for PIPEn.

The saved index of PIPE is written back at (5) if required.

#### (3) Change the index of PIPE

Change the index of PIPE in PIPE\_COM.PIPE\_NUM[4:0] to that of PIPE which generates the interrupt.

- PIPE\_COM.PIPE\_NUM[4:0] = the index of PIPE

#### (4) Check the interrupt factor of PIPEn

See the interrupt status register for PIPEn (Pn\_INT\_STA) to know what factor at PIPEn is the cause of the interrupt.

Note that Pn\_INT\_STA register shows the interrupt status of PIPE which is designated by the index of PIPE in

PIPE\_COM.PIPE\_NUM[4:0].

Then clear the status bit in interrupt status register.

If it is required to remember the interrupt factor in main process, prepare the variable to remember it.

(5) Write back the index of PIPE

When the software exits the interrupt handler, write back the saved index of PIPE at (2) to PIPE\_COM.PIPE\_NUM[4:0] if required.

- PIPE\_COM.PIPE\_NUM[4:0] = the saved index of PIPE at (2)

(6) Operation for the factor of interrupt

The firmware does the operation required for the factor of interrupt after it returns to main process. In order to remember the factor, use the variable as noted at (1) and (4). After completing the operation, initialize the variable.

Especially note that it is prohibited to change the index of PIPE until read of the whole packet from P0\_READ/Pn\_READ or write of it to P0\_WRITE/Pn\_WRITE is completed.

If the interrupt due to PIPEn event is asserted (it can be known by USB\_INT\_STA\_2 register) but read of the whole packet from P0\_READ/Pn\_READ or write of it to P0\_WRITE/Pn\_WRITE has been started, wait for the completion of read or write of the packet. Then change PIPE\_COM.PIPE\_NUM[4:0] to see the factor of interrupt at PIPEn.

See **Section 34.6.6.1, Prohibitions of Register Access** for details.

## (2) USB Connection

The operation required for USB connection is described here.

Figure 34.6-21 USB Connection Flow

## (1) Clear USB\_INT\_STA\_1.VBUS\_CNG\_STA

When VBUS status changes, USB\_INT\_STA\_1.VBUS\_CNG\_STA is asserted. It is notified on an interrupt if enabled. If it is asserted, write 1 to USB\_INT\_STA\_1.VBUS\_CNG\_STA to clear.

- USB\_INT\_STA\_1.VBUS\_CNG\_STA = 1 (Clearing the event that the VBUS status is changed)

## (2) Wait until VBUS becomes stable

In this subsection the device is assumed to be in disconnected state first. Therefore, it is required to check VBUS status in order to know if the device is really connected or not, because the change of VBUS status might be caused by noise.

To know VBUS status, USB\_STA.VBUS\_STA is available. If it shows 1, VBUS voltage level is valid and it means that the device is connected at present.

But VBUS voltage level is supposed to be unstable due to chattering just after the device is connected to host or hub. VBUS level will swing between 1 and 0 (therefore, USB\_STA.VBUS\_STA will also swing) for a while. During the chattering time, it is difficult to know the status of USB connection. Therefore, it is required to wait for VBUS to become stable. Wait for several dozens of milli-second in order to remove the influence of chattering of VBUS level.

If USB\_INT\_ENA\_1.VBUS\_CNG\_ENA is enabled during the chattering time, there might be many interrupts caused by the swing of VBUS level. Disable USB\_INT\_ENA\_1.VBUS\_CNG\_ENA to prevent that the software is annoyed at the swing of VBUS level for the chattering time.

- USB\_INT\_ENA\_1.VBUS\_CNG\_ENA = 0 (The change of VBUS is masked)

## (3) Is USB\_STA.VBUS\_STA = 1?

Check USB\_STA.VBUS\_STA to know whether the interrupt is caused by the change of VBUS level or merely noise. If USB\_STA.VBUS\_STA = 1, it means new USB connection. But if it shows 0, the interrupt detected at (1) would be caused by noise.

## NOTE

If the device is frequently unconnected even when USB\_STA.VBUS\_STA = 1 is confirmed at this point, increase the wait time at (2). In that case, it might take more time to stabilize VBUS level.

## (4) Is connection required?

If device requires to be connected, proceed to (5) to request the connection.

It is possible to insert the grace time here before the connection. The software can use the grace time for the preparation of the connection or other use.

## (5) Resume USB3.1-PHY

If USB3.1-PHY is in the power down state and PLL is suspended, resume USB3.1-PHY so that it provides USB3.1 clock.

See **Section 34.6.5.8(6), USB3.1-PHY (PLL) Wakeup Process** for details.

## (6) Start the operation for USB3.1 connection

Start the connecting operation as USB3.1 device when it is confirmed that device is connected to host.

- USB\_COM\_CON.EP0\_EN = 1 (PIPE0 is enabled)
- USB\_COM\_CON.SPD\_MODE = 0 (SS mode is requested)
- SSIFLINKSET3.SSIF\_NUM\_RDET[3:0] = 8h (The number of trial for Rx.Detect = 8)
- USB\_COM\_CON.RX\_DETECTION = 1 (RxDetect is started)
- USB30\_CON.B3\_CONNECT = 1 (Starting the connection process for SS)

- USB\_INT\_ENA\_1.B3\_LUPSUCS\_ENA = 1 (Interrupt due to the success of link up is enabled)
- USB\_INT\_ENA\_1.B3\_DISABLE\_ENA = 1 (Interrupt due to the failure of link up is enabled)

Besides, if USB\_INT\_ENA\_1.SPEED\_ENA is enabled, the interrupt that SPEED state of USB is changed is asserted after LTSSM enters U0 as SS device or bus reset and chirp are completed as HS or FS device.

- USB\_INT\_ENA\_1.SPEED\_ENA = 1 (Interrupt of SPEED state is enabled)

(7) Does USB3.1 connection succeed?

As the result of the trial for USB3.1 connection, one of USB\_INT\_STA\_1.B3\_LUPSUCS\_STA or USB\_INT\_STA\_1.B3\_DISABLE\_STA is asserted. USB\_INT\_STA\_1.B3\_LUPSUCS\_STA means that the link up process of LTSSM has been successfully done and LTSSM is in U0. USB\_INT\_STA\_1.B3\_DISABLE\_STA means that the link up process of LTSSM has failed and LTSSM is in SS.Disabled. When they are asserted, an interrupt is generated if enabled.

- Check USB\_INT\_STA\_1.B3\_LUPSUCS\_STA = 1 or USB\_INT\_STA\_1.B3\_DISABLE\_STA = 1

After the confirmation above, write 1 to USB\_INT\_STA\_1.B3\_LUPSUCS\_STA or USB\_INT\_STA\_1.B3\_DISABLE\_STA to clear them.

- Write 1 to USB\_INT\_STA\_1.B3\_LUPSUCS\_STA if asserted (Clearing the event that the link up has succeeded)
- Write 1 to USB\_INT\_STA\_1.B3\_DISABLE\_STA if asserted (Clearing the event that USB3.1 connection has failed)

If USB\_INT\_STA\_1.B3\_LUPSUCS\_STA is asserted, it means USB3.1 connection is successful, proceed to (8). If USB\_INT\_STA\_1.B3\_DISABLE\_STA is asserted, it means USB3.1 connection has failed, proceed to (9).

(8) Transition to default state

After the connecting operation has been successfully completed, enable the detection of control transfer at PIPE0 (endpoint 0). At the same time, the interrupts required for the operation mode should be enabled. An example for those cases are shown below. If there are other interrupts required for the usage of core, enable them as well.

- USB\_INT\_ENA\_2.PIPE0\_INT\_ENA = 1 (Interrupt at PIPE0 is enabled)
- All bits in P0\_INT\_ENA register should be enabled (All interrupt factors for PIPE0 are enabled)

If the interrupt due to the change of USB SPEED state is enabled at (6), the interrupt is asserted when USB3.1 or USB2.0 connection is established. See USB\_STA.SPEED[1:0] to know which speed the device is acting as. Then set the bits below according to the speed state.

In this state, the device is acting as USB3.1 device.

- USB\_INT\_ENA\_1.B3\_HOTRST\_ENA = 1 (Interrupt due to hot reset is enabled)
- USB\_INT\_ENA\_1.B3\_WRMIRST\_ENA = 1 (Interrupt due to warm reset is enabled)

And it is recommended to disable USB2.0 setting explicitly as below for good interoperability to USB3.0 Host.

- USB20\_CON.B2\_CONNECT = 0 (USB2.0 connection is disabled)
- USB20\_CON.B2\_PUE = 0 (Pull up of D+ is disabled)

(9) Resume USB2.0-PHY

If USB2.0-PHY is in the power down state and PLL is suspended, resume USB2.0-PHY so that it provides USB2.0 clock.

See **Section 34.6.5.8(10), USB2.0 PHY (PLL) Wakeup Process** for details.

## (10) Start USB2.0 connection

Start the connecting operation as USB2.0 device. Note that USB30\_CON.B3\_CONNECT is still 1. USB3.1 connection might be tried again after USB2.0 bus reset.

- In case of USB\_INT\_STA\_1.B3\_POLLING\_STA = 1 (it indicates connecting with USB3.1 Host), DisabledCount++, and write 1 to USB\_INT\_STA\_1.B3\_POLLING\_STA.

For interoperability, it is recommended to include “B3\_POLLING\_STA = 1” in the condition to increment DisabledCount.

About DisabledCount, see **Section 34.6.5.3(6), USB2.0 Bus Reset Process** for details.

- USB\_COM\_CON.EP0\_EN = 1 (PIPE0 is enabled: this field is already enabled at (6))
- USB\_COM\_CON.SPD\_MODE = 1 (USB2.0 mode is requested)
- USB20\_CON.B2\_PUE = 1 (Pull up on D+ is enabled)
- USB20\_CON.B2\_CONNECT = 1 (Starting the connection process for USB2.0)

## (11) Is USB2.0 bus reset requested?

When USB2.0 bus reset comes, go to USB2.0 bus reset process. See **Section 34.6.5.3(6), USB2.0 Bus Reset Process** for details.

### (3) USB Disconnection

The operation required for USB disconnection is described here.

Figure 34.6-22 USB Disconnection Flow

(1) Is USB\_STA.VBUS\_STA = 0?

If USB\_STA.VBUS\_STA = 0b (it notifies on USB\_INT\_STA\_1.VBUS\_CNG\_STA for example), the device is disconnected.

(2) Resume USB20/USB31-PHYs Process

If USB2.0-PHY is in the power down state and PLL is suspended, resume USB2.0-PHY so that it provides USB2.0 clock.

See **Section 34.6.5.8(10), USB2.0 PHY (PLL) Wakeup Process** for details.

If USB3.1-PHY is in the power down state and PLL is suspended, resume USB3.1-PHY so that it provides USB3.1 clock.

See **Section 34.6.5.8(6), USB3.1-PHY (PLL) Wakeup Process** for details.

(3) Initialize the settings

If the device is disconnected, initialize the settings below.

- USB20\_CON.B2\_PUE = 0 (D+ pull up is disabled)
- USB20\_CON.B2\_CONNECT = 0 (the request of connection as HS or FS device is disabled)
- USB30\_CON.B3\_CONNECT = 0 (the request of connection as SS device is disabled)
- USB\_COM\_CON.CONF = 0 (the device is in unconfigured state)

PIPEs should be initialized as well.

- USB\_COM\_CON.PIPE\_CLR = 1 (PIPE is initialized)

\* Make sure that USB\_COM\_CON.PIPE\_CLR returns to 0 after setting USB\_COM\_CON.PIPE\_CLR = 1.

(4) Place PHYs in low power states

It is recommended to place USB3.1-PHY and USB2.0-PHY in low power state and PLLs in them are suspended in order to reduce the power consumption.

If USB3.1-PHY(PLL) is stopped, refer to **Section 34.6.5.8(1), Suspend in USB3.1 (Transition of State from U0 to U3)** (3),(4),(5). In this case, “U3 state” should be replaced with “disconnected state (SS.Disabled)”.

Note that the values of USB30\_CON.POW\_SEL[2:0] are different in U3 and disconnected state. See **Section 34.6.3.3(3), USB30 Control Register (USB\_PERI\_USB30\_CON)** for details.

If USB2.0-PHY(PLL) is stopped, refer to **Section 34.6.5.8(7), Suspend in USB2.0** (2).

#### (4) Warm Reset Process

The operation required when warm reset is detected is described here.

Figure 34.6-23 Warm Reset Process Flow

(1) Clear USB\_INT\_STA\_1.B3\_WRM\_RST\_STA

When an interrupt is asserted and USB\_INT\_STA\_1.B3\_WRM\_RST\_STA is set to 1, it means that USB3PERI receives warm reset. Write 1 to USB\_INT\_STA\_1.B3\_WRM\_RST\_STA in order to clear it.

- Interrupt due to USB\_INT\_STA\_1.B3\_WRM\_RST\_STA is generated
- Check that USB\_INT\_STA\_1.B3\_WRM\_RST\_STA = 1
- USB\_INT\_STA\_1.B3\_WRM\_RST\_STA = 1 (Clearing the event that warm reset is asserted)

(2) Complete the process of PIPE

Basically, as warm reset is requested when the device is just connected or when host and the device cannot communicate, it is unlikely that the device is executing data transfer when warm reset comes.

But if it is doing, stop the process of data transfer if it is being executed.

AXI\_COM.MST\_WAIT0 can be used to suspend the transfer.

- AXI\_CON.MST\_WAIT0 = 1 (DMA transfer at AXI-IF is requested to be suspended)

See AXI\_STA.DMA\_TRANS0 to know whether the transfer is really suspended or not. If the transfer is suspended, then clear DMA\_Ch0\_CONx.PRD\_ENx to 0.

- DMA\_Ch0\_CONx.PRD\_ENx = 0 (DMA transfer in AXI-IF is disabled)

(3) Reset EPC

Set the registers as follows in order to initialize EPC. In addition to the operations, clear all interrupt statuses.

- USB\_COM\_CON.CONF = 0
- USB\_COM\_CON.EP0\_EN = 0
- USB\_COM\_CON.PIPE\_CLR = 1 (PIPE is initialized)  
\* Make sure that USB\_COM\_CON.PIPE\_CLR returns to 0 after setting USB\_COM\_CON.PIPE\_CLR = 1.
- Write 1 to all interrupt status bits in order to clear them.
- SSIFCMD.SSIF\_UDIR[1:0] = 11b (The initiation of LGO\_U1/LGO\_U2 due to direct request is disabled.)
- SSIFCMD.SSIF\_UREQ[1:0] = 11b (The initiation of LGO\_U1/LGO\_U2 due to timeout is disabled.)

(4) Start the operation for USB3.1 connection

Start the connecting operation as USB3.1 device.

- SSIFLINKSET3.SSIF\_NUM\_RDET[3:0] = 8h (The number of trial of Rx.Detect=8 )
- USB\_COM\_CON.EP0\_EN = 1
- USB\_COM\_CON.SPD\_MODE = 0
- USB30\_CON.B3\_CONNECT = 1 (Starting the connection process for USB3.1)
- USB\_INT\_ENA\_1.SPEED\_ENA = 1 (Interrupt of SPEED state is enabled)

If USB3.1 connection is established (the device works as USB3.1 device) before warm reset comes, the fields already has the values above. But SSIFLINKSET3.SSIF\_NUM\_RDET[3:0] might be changed. Set the field again to make sure.

(5) Check the status of USB3.1 connection

Check the status of connection process as USB3.1 device on the bits below.

If USB\_INT\_STA\_1.B3\_LUPSUCS\_STA is asserted, USB3.1 connection is completed successfully. Clear the bit and proceed to (6).

If USB\_INT\_STA\_1.B3\_DISABLE\_STA is asserted, the link up process as USB3.1 device has failed. Clear the bit and proceed to (7).

- Interrupt due to USB\_INT\_STA\_1.B3\_LUPSUCS\_STA or USB\_INT\_STA\_1.B3\_DISABLE\_STA is asserted
- Check whether USB\_INT\_STA\_1.B3\_LUPSUCS\_STA = 1 or not (The link up succeeded or not)
- Check whether USB\_INT\_STA\_1.B3\_DISABLE\_STA = 1 or not (The link up failed or not)
- Write 1 to the asserted bit to clear (Clearing the event that the link up succeeded or failed)

(6) Transition to default state as USB device

After the connecting operation has been successfully done, enable the detection of control transfer at PIPE0 (endpoint 0). At the same time, the interrupts required for the operation mode should be enabled. Examples for those cases are shown below. If there are other interrupts required for the usage of core, enable them as well.

- USB\_INT\_ENA\_2.PIPE0\_INT\_ENA = 1 (Interrupt at PIPE0 is enabled)
- All bits in P0\_INT\_ENA register should be enabled (All interrupt factors for PIPE0 are enabled)

If the interrupt due to the change of USB SPEED state is enabled at (3), the interrupt is asserted when USB3.1 or USB2.0 connection is established. See USB\_STA.SPEED[1:0] to know which speed the device is acting as. Then set the bits according to SPEED state as follows.

[when acting as USB3.1 device]

- USB\_INT\_ENA\_1.B3\_HOTRST\_ENA = 1 (Interrupt due to hot reset is enabled)
- USB\_INT\_ENA\_1.B3\_WRMIRST\_ENA = 1 (Interrupt due to warm reset is enabled)

And it is recommended to disable USB2.0 setting explicitly as below for good interoperability to USB3.0 Host.

- USB20\_CON.B2\_CONNECT = 0 (USB2.0 connection is disabled)
- USB20\_CON.B2\_PUE = 0 (Pull up of D+ is disabled)

[when acting as USB2.0 device]

- USB\_INT\_ENA\_1.B2\_SPND\_ENA = 1 (Interrupt due to USB2.0 suspend is enabled)
- USB\_INT\_ENA\_1.B2\_L1SPND\_ENA = 1 (Interrupt due to L1 suspend is enabled)
- USB\_INT\_ENA\_1.B2\_USBRST\_ENA = 1 (Interrupt due to USB2.0 bus reset is enabled)

(7) Resume USB2.0-PHY

If USB20 PHY is in the power down state and PLL is suspended, resume PLL so that it provides USB2.0 clock.

(8) Start the operation for USB2.0 connection

Start the connecting operation as USB2.0 device when USB3.1 connection is failed at (6).

- USB\_COM\_CON.EP0\_EN = 1
- USB\_COM\_CON.SPD\_MODE = 1
- USB20\_CON.B2\_PUE = 1b (Pull up on D+ is enabled)
- USB20\_CON.B2\_CONNECT = 1 (Starting the connection process for USB2.0)

If device is acting as USB2.0 device and USB3.1- PHY is expected to be in low power state, set it in low power state here. But note that USB2.0 bus reset will come when the operation for USB2.0 connection is started and it is required to try USB3.1 connection again collaterally. It means that USB3.1-PHY cannot be placed in low power state before USB2.0 connection is established. Make sure that the device is acting as USB2.0 device and the sequence of USB2.0 bus reset has already been done before setting USB3.1-PHY in low power state.

## (5) Hot Reset Process

The operation required when hot reset is detected is described here.

Figure 34.6-24 Hot Reset Process Flow

### (1) Clear USB\_INT\_STA\_1.B3\_HOTRST\_STA

When an interrupt is asserted and USB\_INT\_STA\_1.B3\_HOTRST\_STA is set to 1, it means that USB3PERI receives hot reset. Write 1 to USB\_INT\_STA\_1.B3\_HOTRST\_STA in order to clear it.

- Interrupt due to USB\_INT\_STA\_1.B3\_HOTRST\_STA is generated
- Check that USB\_INT\_STA\_1.B3\_HOTRST\_STA = 1
- USB\_INT\_STA\_1.B3\_HOTRST\_STA = 1 (Clearing the event that hot reset is asserted)

### (2) Complete the process of PIPE

Since hot reset comes during the training sequence, it is unlikely that the device is executing data transfer when hot reset comes.

But if it is doing, stop the process of data transfer if it is being executed.

AXI\_COM.MST\_WAIT0 can be used to suspend the transfer.

- AXI\_CON.MST\_WAIT0 = 1 (DMA transfer at AXI-IF is requested to be suspended)

See AXI\_STA.DMA\_TRANS0 to know whether the transfer is really suspended or not. If the transfer is suspended, then clear DMA\_Ch0\_CONx.PRD\_ENx to 0.

- DMA\_Ch0\_CONx.PRD\_ENx = 0 (DMA transfer in AXI-IF is disabled)

### (3) Reset EPC

Set the registers as follows in order to initialize EPC. In addition to the operations, clear all interrupt statuses.

- USB\_COM\_CON.CONF = 0
- USB\_COM\_CON.EP0\_EN = 0
- USB\_COM\_CON.PIPE\_CLR = 1 (PIPE is initialized)
  - \* Make sure that USB\_COM\_CON.PIPE\_CLR returns to 0 after setting USB\_COM\_CON.PIPE\_CLR = 1.
- Write 1 to all interrupt status bits in order to clear them.

- SSIFCMD.SSIF\_UDIR[1:0] = 11b (The initiation of LGO\_U1/LGO\_U2 due to direct request is disabled.)
- SSIFCMD.SSIF\_UREQ[1:0] = 11b (The initiation of LGO\_U1/LGO\_U2 due to timeout is disabled.)

(4) Complete Hot Reset

Set the bit below to complete hot reset.

- USB\_COM\_CON.EP0\_EN = 1
- USB30\_CON.B3\_HOTRST\_CMP = 1

By setting USB30\_CON.B3\_HOTRST\_CMP = 1, LTSSM state of USB3PERI transits from HotReset.Active to HotReset.Exit.

Setting B3\_HOTRST\_CMP = 1 allows the device to transit to HotReset.Exit from HotReset.Active. This process should be completed within 12 ms from detecting the start of HotReset at (1).

NOTE

The function of hot reset of device is tested in TD.7.28 of link layer test for compliance. The notations for the test are described here.

The downstream port can initiate a hot reset. When it transmits TS2 ordered sets with Reset bit asserted, the device shall respond by sending TS2 ordered sets with Reset bit asserted. When the device completes the operation for reset, it sends TS2 ordered set with Reset bit deasserted. The downstream port shall respond by sending TS2 ordered sets with Reset bit deasserted. Once both ports receive the TS2 ordered sets with Reset bit deasserted, it means the completion of hot reset and they shall exit from the hot reset state.

Note that USB3PERI automatically starts to transmit TS2 ordered sets with Reset bit asserted when it receives TS2 ordered sets with Reset bit asserted (that is, hot reset requested from downstream port).

But it is required to set USB30\_CON.B3\_HOTRST\_CMP in order to return TS2 ordered sets with Reset bit deasserted, if USB3PERI enters the state it returns TS2 ordered set with Reset bit asserted once. If there is any operation required for reset, it should be done before USB30\_CON.B3\_HOTRST\_CMP is set. It is notified on USB\_INT\_STA\_1.B3\_HOTRST\_STA that USB3PERI receives TS2 ordered sets with Reset bit asserted and starts to respond to them.

If the device does not return TS2 ordered sets with Reset bit asserted and hot reset isn't completed with tHotResetActiveTimeout ( = 12 ms), the device fails in the test of TD.7.28.

If the device including USB3PERI never deasserts Reset bit in TS2 ordered set, the software may not recognize that USB\_INT\_STA\_1.B3\_HOTRST\_STA is asserted. In the test of TD.7.28, TS2 ordered sets with Reset bit asserted may come immediately after the device is connected to the downstream port. That case does not occur in normal operation. If the software masks interrupts except that due to the change of VBUS (USB\_INT\_STA\_1.VBUS\_CNG\_STA) immediately after the device is connected, the software may not be able to know USB\_INT\_STA\_1.B3\_HOTRST\_STA asserted. It is recommended to enable interrupts due to USB\_INT\_STA\_1.VBUS\_CNG\_STA and USB\_INT\_STA\_1.B3\_HOTRST\_STA just after the device is connected.

### (6) USB2.0 Bus Reset Process

The operation required when USB2.0 bus reset is detected is described here.

There are two cases assumed as that USB2.0 bus reset comes.

- Device is just connected but fails in USB3.1 connection. USB2.0 connection is in progress.
- Device is working in HS or FS but host requests USB2.0 bus reset for some reason.

This case also means device has failed in USB3.1 connection once.

That is, USB2.0 bus reset does not come when device works in SS, but it comes when device works in HS or FS.

USB2.0 bus reset means not only the reset as USB2.0 device but also the retry of USB3.1 connection for USB3.1 device. See **Section 34.6.4.2, USB3.1/USB2.0 connection** for the description of USB3.1 specification.

Figure 34.6-25 USB2.0 Bus Reset (switching from USB2.0 to USB3.1) Flow

The software is required to prepare the variable “DisabledCount”. The variable means the number of failures in link up. The initial value of DisabledCount is 0 and it is initialized to 0 when one of the following conditions is satisfied.

- VBUS is disabled (No power is provided from VBUS).
- Port configuration exchange completes successfully.
- Power is removed.

Furthermore, being requested USB2.0 bus reset means that the device has already pulled up D+ (as HS or FS device) and has been detected by host. It is assumed that the software has already set USB20\_CON.B2\_CONNECT = 1 when USB2.0 bus reset comes.

(1) Clear USB\_INT\_STA\_1.B2\_USBRST\_STA

When an interrupt is asserted and USB\_INT\_STA\_1.B2\_USBRST\_STA is set to 1, it means that USB3PERI receives USB2.0 bus reset. Write 1 to USB\_INT\_STA\_1.B2\_USBRST\_STA in order to clear it.

(2) Complete the process of PIPE

Basically, as USB2.0 bus reset is requested when the device is just connected or when host and the device cannot communicate, it is unlikely that the device is executing data transfer when bus reset comes.

But if it is doing, stop the process of data transfer if it is being executed.

AXI\_COM.MST\_WAIT0 can be used to suspend the transfer.

- AXI\_CON.MST\_WAIT0 = 1 (DMA transfer at AXI-IF is requested to be suspended)

See AXI\_STA.DMA\_TRANS0 to know whether the transfer is really suspended or not. If the transfer is suspended, then clear DMA\_Ch0\_CONx.PRD\_ENx to 0.

- DMA\_Ch0\_CONx.PRD\_ENx = 0 (DMA transfer in AXI-IF is disabled)

(3) Reset EPC

Set the registers as follows in order to initialize EPC. In addition to the operations, clear all interrupt statuses.

- USB\_COM\_CON.CONF = 0
- USB\_COM\_CON.EP0\_EN = 0
- USB\_COM\_CON.PIPE\_CLR = 1 (PIPE is initialized)  
\* Make sure that USB\_COM\_CON.PIPE\_CLR returns to 0 after setting USB\_COM\_CON.PIPE\_CLR = 1.
- USB20\_CON.B2\_TSTMOD[2:0] = 0h (if test mode is set)
- USB20\_CON.B2\_TSTMOD\_EN = 0 (if test mode is set)
- Write 1 to all interrupt status bits in order to clear them.

(4) Resume USB2.0-PHY

It is assumed that the device works in HS or FS, but the device might be in suspended state and PLL in USB2.0-PHY might be stopped when USB2.0 bus reset comes.

In that case resume USB2.0-PHY so that it provides USB2.0 clock. USB3.1 connection might be requested depending on the value of DisabledCount, but the pull up of D+ for USB2.0 connection is still valid and USB2.0 connection is tried immediately when USB3.1 connection fails. That is, USB2.0-PHY clock is required regardless of the value of DisabledCount.

(5) Is DisabledCount < 3?

If DisabledCount < 3, it means the device state is in USDPORT.Powered on due to USB2.0 bus reset and the device requests USB3.1 connection. Proceed to (6).

If DisabledCount = 3, it means the device state is in USDPORT.Disabled\_Error and the device does not request USB3.1 connection. Proceed to (10).

## (6) Resume USB3.1-PHY

If USB3.1-PHY is in the power down state and PLL is suspended, resume USB3.1-PHY so that it provides USB3.1 clock.

## (7) Start USB3.1 connection

As DisbledCount < 3, USB3.1 connection is tried again.

If USB2.0 bus reset is the first one just after the device is connected but fails in USB3.1 connection, most of the fields below has already been set at (6) in **Section 34.6.5.3(2), USB Connection**. In that case, the settings for USB2.0 connection at (10) in **Section 34.6.5.3(2), USB Connection** should be still active as they are because USB2.0 connection might be required when USB3.1 connection fails.

- USB\_COM\_CON.EP0\_EN = 1 (PIPE0 is enabled)
- USB\_COM\_CON.SPD\_MODE = 0 (USB3.1 mode is requested)
- SSIFLINKSET3.SSIF\_NUM\_RDET[3:0] = 1h (The number of trial for Rx.Detect=1)
- USB\_COM\_CON.RX\_DETECTION = 1 (RxDetect is started)
- USB30\_CON.B3\_CONNECT = 1 (Starting the connection process for USB3.1)
- USB\_INT\_ENA\_1.B3\_LUPSUCS\_ENA = 1 (Interrupt due to the success of link up is enabled)
- USB\_INT\_ENA\_1.B3\_DISABLE\_ENA = 1 (Interrupt due to the failure of link up is enabled)
- USB\_INT\_ENA\_1.SPEED\_ENA = 1 (Interrupt of SPEED state is enabled)

The difference with (6) in **Section 34.6.5.3(2), USB Connection** is that the SSIFLINKSET3.SSIF\_NUM\_RDET[3:0] = 1h although it is set to 8h at (6) in **Section 34.6.5.3(2), USB Connection**. It means that the device can do only one trial of Rx detection.

## (8) Does USB3.1 connection succeed?

As the result of the trial for USB3.1 connection, one of USB\_INT\_STA\_1.B3\_LUPSUCS\_STA or USB\_INT\_STA\_1.B3\_DISABLE\_STA is asserted. USB\_INT\_STA\_1.B3\_LUPSUCS\_STA means that the link up process of LTSSM has been successfully done and LTSSM is in U0. USB\_INT\_STA\_1.B3\_DISABLE\_STA means that the link up process of LTSSM has failed and LTSSM is in SS.Disabled. When they are asserted, an interrupt is generated if enabled.

- Check USB\_INT\_STA\_1.B3\_LUPSUCS\_STA = 1 or USB\_INT\_STA\_1.B3\_DISABLE\_STA = 1

After the confirmation above, write 1 to USB\_INT\_STA\_1.B3\_LUPSUCS\_STA or USB\_INT\_STA\_1.B3\_DISABLE\_STA to clear them.

- Write 1 to USB\_INT\_STA\_1.B3\_LUPSUCS\_STA if asserted (Clearing the event that the link up has succeeded)
- Write 1 to USB\_INT\_STA\_1.B3\_DISABLE\_STA if asserted (Clearing the event that USB3.1 connection has failed)

If USB\_INT\_STA\_1.B3\_LUPSUCS\_STA is asserted, it means USB3.1 connection is successful, proceed to (9). If USB\_INT\_STA\_1.B3\_DISABLE\_STA is asserted, it means USB3.1 connection has failed, proceed to (10).

## (9) Settings as USB3.1 device

After the connecting operation as SS device has been successfully completed, disable USB2.0 connection. It is defined in USB3.1 specification that USB2.0 connection should be disabled within tUSB2SwitchDisconnect (= 1ms) after Far End Receiver Termination is detected and LTSSM enters Polling.

- USB20\_CON.B2\_CONNECT = 0 (USB2.0 connection is disabled)
- USB20\_CON.B2\_PUE = 0 (Pull up of D+ is disabled)

Then enable the detection of control transfer at PIPE0 (endpoint 0). At the same time, the interrupts required for the operation mode should be enabled. An example for that cases are shown below. If there is another interrupt required for the usage of core, enable it as well.

- USB\_INT\_ENA\_2.PIPE0\_INT\_ENA = 1 (Interrupt at PIPE0 is enabled)
- All bits in P0\_INT\_ENA register should be enabled (All interrupt factors for PIPE0 are enabled)

As the device is working as SS device, interrupts due to hot reset or warm reset shall be enabled.

- USB\_INT\_ENA\_1.B3\_HOTRST\_ENA = 1 (Interrupt due to hot reset is enabled)
- USB\_INT\_ENA\_1.B3\_WRMIRST\_ENA = 1 (Interrupt due to warm reset is enabled)

When the port configuration is completed, DisabledCount is reset to 0.

If USB2.0 clock is not needed, USB2.0-PHY can be suspended. See **Section 34.6.5.8(7), Suspend in USB2.0** for details.

(10) Start USB2.0 connection

Since USB3.1 connection has failed, disable USB3.1 connection.

- USB30\_CON.B3\_CONNECT = 0
- In case of USB\_INT\_STA\_1.B3\_POLLING\_STA= 1 (it indicates connecting with USB3.1 Host), DisabledCount++, and write 1 to USB\_INT\_STA\_1.B3\_POLLING\_STA.

For interoperability, it is recommended to include “B3\_POLLING\_STA= 1” in the condition to increment DisabledCount.

Then, start USB2.0 connection.

The most of the fields below has already set, but USB\_COM\_CON.SPD\_MODE is set for USB3.1 connection at (7), so it should be changed for USB2.0 connection.

- USB\_COM\_CON.EP0\_EN = 1 (PIPE0 is enabled: this field is already enabled at (6))
- USB\_COM\_CON.SPD\_MODE = 1 (USB2.0 mode is requested)
- USB20\_CON.B2\_PUE = 1 (Pull up on D+ is enabled)
- USB20\_CON.B2\_CONNECT = 1 (Starting the connection process for USB3.1)
- USB\_INT\_ENA\_1.SPEED\_ENA = 1 (Interrupt of SPEED state is enabled)

(11) Does USB2.0 connection succeed?

After USB2.0 bus reset and chirp, the device works as HS or FS device. For USB2.0 connection, there is no link training as that in USB3.1 connection, so it is assumed to be always completed successfully.

(12) Setting as USB2.0 device

After the connecting operation as HS or FS has been successfully done, enable the detection of control transfer at PIPE0 (endpoint 0). At the same time, the interrupts required for the operation mode should be enabled. Examples for those cases are shown below. If there are other interrupts required for the usage of core, enable them as well.

- USB\_INT\_ENA\_2.PIPE0\_INT\_ENA = 1 (Interrupt at PIPE0 is enabled)
- All bits in P0\_INT\_ENA register should be enabled (All interrupt factors for PIPE0 are enabled)

If the interrupt due to the change of USB SPEED state is enabled at (10), the interrupt is asserted when USB2.0 connection is established. See USB\_STA.SPEED[1:0] to know which speed the device is acting as. Then set the bits according to SPEED state as follows.

[when acting as USB2.0 device]

- USB\_INT\_ENA\_1.B2\_SPND\_ENA = 1 (Interrupt due to USB2.0 suspend is enabled)

- USB\_INT\_ENA\_1.B2\_L1SPND\_ENA = 1 (Interrupt due to L1 suspend is enabled)
- USB\_INT\_ENA\_1.B2\_USBRST\_ENA = 1 (Interrupt due to USB2.0 bus reset is enabled)

### 34.6.5.4 Control Transfer

The operation for control transfer is described here.

Figure 34.6-26 Control Transfer Process Flow

#### (1) Clear P0\_INT\_STA.P0\_SETUP\_STA

When an interrupt is asserted and P0\_INT\_STA.P0\_SETUP\_STA is set to 1, it means that USB3PERI has received setup data. Write 1 to P0\_INT\_STA.P0\_SETUP\_STA in order to clear it.

- Interrupt due to P0\_INT\_STA.P0\_SETUP\_STA is generated
- Check that P0\_INT\_STA.P0\_SETUP\_STA = 1
- P0\_INT\_STA.P0\_SETUP\_STA = 1 (Clearing the event setup data has been received)

In case the status bits related to control transfer are set, they should be cleared as follows.

- P0\_INT\_STA.P0\_STSST\_STA = 1
- P0\_INT\_STA.P0\_STSED\_STA = 1
- P0\_INT\_STA.P0\_RCVNL\_STA = 1
- P0\_INT\_STA.P0\_ERDY\_STA = 1
- P0\_INT\_STA.P0\_FLOW\_STA = 1
- P0\_INT\_STA.P0\_STALL\_STA = 1
- P0\_INT\_STA.P0\_NRDY\_STA = 1

The data buffer for PIPE0 should also be cleared just in case data of previous transfer is left in the buffer.

- P0\_CON.P0\_BCLR = 1 (Clearing data buffer for PIPE0)

#### (2) Read setup data

Read setup data from STUP\_DAT\_0 and STUP\_DAT\_1 registers.

## (3) Is setup data invalid?

In case that setup data is invalid, respond with STALL. Set P0\_ST\_RES[1:0], P0\_OT\_RES[1:0] and P0\_IN\_RES[1:0] in P0\_CON register to return STALL response in that case.

- P0\_CON.P0\_RES\_WEN = 1
- P0\_CON.P0\_ST\_RES[1:0] = 10b (forced STALL response)
- P0\_CON.P0\_OT\_RES[1:0] = 10b (forced STALL response)
- P0\_CON.P0\_IN\_RES[1:0] = 10b (forced STALL response)

With the settings above, USB3PERI returns STALL for all requests (IN, OUT or STATUS) to PIPE0. Whenever USB3PERI responds with STALL, P0\_INT\_STA.P0\_STALL\_STA is asserted. Since USB device is not required to change the response from PIPE0 until new setup data comes to PIPE0 as noted in (5) or any reset comes in that case, an interrupt due to P0\_INT\_STA.P0\_STALL\_STA can be ignored (that is, it can be masked).

## (4) Recovery from STALL

If host wants to recovery the status, it will send ClearFeature(ENDPOINT\_HALT) or other request. The device should initialize the response for it.

When host sends new setup data including it requests ClearFeature(ENDPOINT\_HALT), P0\_INT\_STA.P0\_SETUP\_STA will be asserted again.

When the assertion of P0\_INT\_STA.P0\_SETUP\_STA is detected (it is notified on an interrupt if enabled), USB3PERI automatically sets P0\_CON.P0\_ST\_RES[1:0], P0\_CON.P0\_OT\_RES[1:0] and P0\_CON.P0\_IN\_RES[1:0] to 00b (NRDY/NAK response). Note that it might take time to decide and prepare a response here. Hence it is assumed that the response is changed to normal one after the decision and the preparation.

If it does not take time, normal responses can be set here.

- New setup data is received. (It is notified on the assertion of P0\_INT\_STA.P0\_SETUP\_STA.)  
(-USB3PERI automatically sets P0\_CON.P0\_\*\_RES[1:0] to 00b, but the software can change them to normal response.)

Then, go back to (1).

## (5) Decode setup data

Decode the content of setup data which is read at (2).

If wLength = 0, no data control process is being requested.

If wLength is not 0 and bmRequestType[7] is 0, control write data process is being requested. Otherwise control read process is being requested.

## (6) No Data Control, Control Write or Control Read process

Refer each subsection as follows.

- a) No Data Control process: Refer to **Section 34.6.5.4(1), No Data Control Process**
- b) Control Write process: Refer to **Section 34.6.5.4(2), Control Write Process**
- c) Control Read process: Refer to **Section 34.6.5.4(3), Control Read Process**

## (7) Set the response at status stage

From (7) to (8) the settings for status stage are described. For the operations required in each process before status stage, refer to **Section 34.6.5.9, Device Requests**. Basically the process requested by setup data should be finished before the device completes the status stage. The status stage might be started before the completion of the process, but the device can put off the completion of the status stage by returning NRDY or NAK.

Set P0\_CON.P0\_ST\_RES[1:0] as follows.

- P0\_CON.P0\_RES\_WEN = 1

- P0\_CON.P0\_ST\_RES[1:0] = 01b (Normal response)

For P0\_CON.P0\_OT\_RES[1:0] and P0\_CON.P0\_IN\_RES[1:0], keep the value set at (6) in case of Control Write process or Control Read process. In case of No Data Control process, they should be set to forced STALL response at the same time as the setting of P0\_CON.P0\_ST\_RES[1:0].

- P0\_CON.P0\_OT\_RES[1:0] = 10b (STALL response)
- P0\_CON.P0\_IN\_RES[1:0] = 10b (STALL response)

(8) Complete Status Stage

Wait for the interrupt due to P0\_INT\_STA.P0\_STSED\_STA, which shows USB3PERI completes the status stage of the control transfer. Confirm P0\_INT\_STA.P0\_STSED\_STA is asserted, and then write 1 to it to clear.

- Interrupt due to P0\_INT\_STA.P0\_STSED\_STA is generated
- Check that P0\_INT\_STA.P0\_STSED\_STA = 1
- P0\_INT\_STA.P0\_STSED\_STA = 1 (Clearing the event that the status stage of control transfer has been completed.)

NOTE

In the specification of USB, it is defined that the sequence of control transfer should be initialized when new setup data is received during control transfer. Device should stop the operation for previous setup data and switch to the operation of new setup data. That case seldom occurs, but the consideration of it is required.

**(1) No Data Control Process**

The operation for no data control transfer is described here.

Figure 34.6-27 No Data Control Transfer Process Flow

**(1) Set the response**

After decoding setup data, set the response for the request.

- P0\_MOD.P0\_DIR = 0 (Direction = OUT)

Select NRDY/NAK response for the status stage until the operation at (2) is completed. If the operation is not needed, USB3PERI can respond with ACK immediately. The final response at the status stage is selected at (7) in the flow of **Section 34.6.5.4, Control Transfer**.

As no data is sent or received in this flow, select STALL response for IN and OUT transfer request. All of the settings below are for P0\_CON register and it allows only 32-bit access, so note that they should be done in one word access.

- P0\_CON.P0\_RES\_WEN = 1
- P0\_CON.P0\_ST\_RES[1:0] = 00b (NRDY/NAK response. ACK response is also selectable.)
- P0\_CON.P0\_OT\_RES[1:0] = 10b (STALL response)
- P0\_CON.P0\_IN\_RES[1:0] = 10b (STALL response)

**(2) Request processing**

If any operation for the request is required, do it here.

See **Section 34.6.5.9, Device Requests** for the operations of major device requests.

## (2) Control Write Process

The operation for control writer transfer is described here.

Figure 34.6-28 Control Write Process Flow

### (1) Set the response

After decoding setup data, set the response for the request.

As control write transfer is requested here, select OUT as the direction of transfer.

Set NRDY/NAK response for the status stage since the data stage has not been finished yet. Set normal response for OUT and STALL response for IN.

- P0\_MOD.P0\_DIR = 0 (Direction = OUT)
- P0\_CON.P0\_RES\_WEN = 1
- P0\_CON.P0\_ST\_RES[1:0] = 00b (NRDY/NAK response)
- P0\_CON.P0\_OT\_RES[1:0] = 01b (normal response)
- P0\_CON.P0\_IN\_RES[1:0] = 10b (STALL response)

### (2) Wait for OUT data

For control write transfer, the software reads each packet in data stage of the transfer through P0\_READ register. When OUT data packet to PIPE0 is received, an interrupt due to P0\_INT\_STA.P0\_BFRDY\_STA is asserted. In that case, write 1 to P0\_INT\_STA.P0\_BFRDY\_STA to clear.

- Interrupt due to P0\_INT\_STA.P0\_BFRDY\_STA is generated
- Check that P0\_INT\_STA.P0\_BFRDY\_STA = 1

- P0\_INT\_STA.P0\_BFRDY\_STA = 1 (Clearing the event that OUT data has been received at PIPE0)

When receiving OUT data packet, P0\_STA.P0\_BUFSTS is also asserted. The meaning of the bit is OUT data packet is ready to be read from P0\_READ register. Polling P0\_STA.P0\_BUFSTS is available to know that OUT data packet has been received for the software as well.

(3) Check the length of received data

Read the following field to know the length of received data.

- Read P0\_LNG.P0\_LENGTH[9:0] (This field shows the number of bytes of received data)

(4) Read OUT data

Read OUT data through P0\_READ register. Note that OUT data in control transfer cannot be read from Data Interface of EPC or cannot be transferred by AXI DMA transfer.

P0\_READ register should be read in a unit of 32-bit. P0\_READ register is updated and the next 32-bit word of received data is shown in P0\_READ register every time it is read. The length of received data is known at (3) and the number of read from P0\_READ register can be calculated from the length. The number of read = the length divided by 4, round-up is required if there is any residue. If there is residue, it also means the last 32-bit word read has one or more unnecessary bytes. In that case, discard unnecessary bytes.

(5) Are all packets received?

If wLength shown in setup data is more than the max packet size in control transfer, it means two or more OUT data packets would come. In that case, repeat the steps from (2) to (4) for the number of packets.

After all of OUT packets have been received and read, set the registers as follows. Note P0\_CON register should be written in a unit of 32-bit and other fields should hold its value. That is, read-modify-write will be required.

- P0\_CON.P0\_RES\_WEN = 1
- P0\_CON.P0\_OT\_RES[1:0] = 10b (STALL response)

(6) Request processing

If any operation for the request is required, do it here.

See **Section 34.6.5.9, Device Requests** for the operations of major device requests.

### (3) Control Read Process

The operation for control read transfer is described here.

Figure 34.6-29 Control Read Process Flow

#### (1) Set the response

After decoding setup data, set the response for the request.

As control read transfer is requested here, select IN as the direction of transfer.

Set NRDY/NAK response for the status stage since the data stage has not been finished yet. Set normal response for IN and STALL response for OUT.

- P0\_MOD.P0\_DIR = 1 (Direction = IN)
- P0\_CON.P0\_RES\_WEN = 1
- P0\_CON.P0\_ST\_RES[1:0] = 00b (NRDY/NAK response)
- P0\_CON.P0\_OT\_RES[1:0] = 10b (STALL response)
- P0\_CON.P0\_IN\_RES[1:0] = 01b (Normal response)

#### (2) Check if buffer is available

For control read transfer, the software writes each packet in data stage of the transfer through P0\_WRITE register. But if there is no space available in the buffer for PIPE0, it cannot write. P0\_STA.P0\_BUFSTS shows if there is available space in the buffer. See the bit before writing IN data packet to P0\_WRITE register.

- Check whether P0\_STA.P0\_BUFSTS = 1 or not

If P0\_STA.P0\_BUFSTS is 0 and there is no available space in the buffer currently, wait until

P0\_STA.P0\_BUFSTS becomes 1 or an interrupt due to P0\_INT\_STA.P0\_BFRDY\_STA is asserted. When IN is selected as the direction of PIPE0 (that is, P0\_MOD.P0\_DIR = 1), P0\_INT\_STA.P0\_BFRDY\_STA is asserted when the buffer for PIPE0 becomes available for new write data.

Therefore, the software can know the timing the buffer for PIPE0 prepares new available space by polling P0\_STA.P0\_BUFSTS or an interrupt due to P0\_INT\_STA.P0\_BFRDY\_STA.

But, Note that P0\_INT\_STA.P0\_BFRDY\_STA is not asserted just after a reset (hardware reset, USB\_COM\_CON.PIPE\_CLR, P0\_CON.P0\_BCLR and P0\_CON.P0\_CLR) and when the software writes the first packet. In that case, since the buffer has available space just after a reset, so the software can write the packet without being notified on an interrupt due to P0\_INT\_STA.P0\_BFRDY\_STA. The software still can see P0\_STA.P0\_BUFSTS in that case.

(3) Write IN data

Write IN data through P0\_WRITE register. Note that IN data in control transfer cannot be written through Data Interface of EPC or cannot be transferred by AXI DMA transfer.

P0\_WRITE register should be written in a unit of 32-bit. The number of write can be calculated as the number of write = the length divided by 4, round-up is required if there is any residue. The written words are concatenated as one packet.

When the length of packet is not multiples of 32-bit, the last word has unnecessary bytes. The last written word should be also written as a 32-bit word. The number of valid bytes in the last word is set in P0\_CON.P0\_BYTE\_EN. Unnecessary bytes in the last word are discarded.

To send the packet, set the registers as follows after the last word has been written.

- P0\_CON.P0\_SEND = 1
- P0\_CON.P0\_BYTE\_EN[1:0] = xxb (the number of valid bytes in last written word)

NOTE

Zero length packet will be sent if P0\_CON.P0\_SEND is set to 1 after P0\_WRITE register is written nothing in the above. In this case, P0\_CON.P0\_BYTE\_EN[1:0] is ignored (it's usually set "00" at the same time P0\_SEND is set).

See **Section 34.6.4.6, Zero Length Packet (ZLP)** about zero length packet.

(4) Are all packets written?

If wLength shown in setup data is more than the max packet size in control transfer, it means two or more IN data packets are required. In that case, repeat the steps from (2) to (3) for the number of packets.

After all of IN packets have been sent, set the registers as follows. Note P0\_CON register should be written in a unit of 32-bit and other fields should hold its value. That is, read-modify-write will be required.

- P0\_CON.P0\_RES\_WEN = 1
- P0\_CON.P0\_IN\_RES[1:0] = 01b (STALL response)

(5) Request processing

If any operation for the request is required, do it here.

See **Section 34.6.5.9, Device Requests** for the operations of major device requests.

### 34.6.5.5 Bulk Transfer

The operation for bulk transfer is described here.

PIPEs other than PIPE0 (PIPE0 is used only for control transfer) can be used for bulk transfer. The settings for bulk transfer are shown below.

- PIPE\_COM.PIPE\_NUM[4:0] = the index of PIPE used for the current bulk transfer
- Pn\_MOD.Pn\_EPNUM[3:0] = the endpoint number of the PIPE
- Pn\_MOD.Pn\_TYPE[1:0] = 10b (bulk transfer)
- Pn\_MOD.Pn\_DIR = the direction of transfer
- Pn\_MOD.Pn\_STREAM = whether the PIPE is used for Stream bulk transfer or not
- Pn\_MOD.Pn\_BOT = whether the PIPE uses BOT or not
- Pn\_MOD.Pn\_ERDY\_CON[1:0] = threshold to send ERDY
- Pn\_RAMMAP.Pn\_BASEAD[13:0] = the base address of buffer assigned for the PIPE
- Pn\_RAMMAP.Pn\_RAMIF[1:0] = the index of RAM interface of the PIPE
- Pn\_RAMMAP.Pn\_MPKT[10:0] = 1024bytes for SS, 512 bytes for HS or 64 bytes for FS
- Pn\_RAMMAP.Pn\_RAMAREA = the size of RAM area assigned for the PIPE
- Pn\_CON.Pn\_DATAIF\_EN = whether Data Interface of EPC or AXI-IF is used or not.
- Pn\_CON.Pn\_EN = 1 (the PIPE is enabled)

These settings are done just after Set Configuration is completed and the device enters configured state. But if the device has only single configuration for each PIPE, these settings can be done after the device is turned on.

### (1) Bulk-IN Process

The normal bulk IN process is described here. See **Section 34.6.5.5(3), Stream Bulk Process** for Stream bulk process.

In this subsection the process to write bulk IN packet through Data Interface of EPC or Pn\_WRITE register is described. DMA transfer as the master function of AXI-IF is available. See **Section 34.6.5.7, DMA Transfer** for the process using DMA transfer.

Figure 34.6-30 Bulk IN Process Flow

#### (1) Change the response mode of the bulk IN PIPE

Change the response mode of the bulk IN PIPE to normal response so that the PIPE can transmit data.

- Pn\_CON.Pn\_RES\_WEN = 1
- Pn\_CON.Pn\_RES[1:0] = 01b (Normal response)

#### (2) Check if buffer is available

Check if buffer for the bulk IN PIPE is available before writing bulk IN packet. Pn\_STA.Pn\_BUFSTS shows if the buffer is available or not.

- Check whether Pn\_STA.Pn\_BUFSTS = 1 or not

If Pn\_STA.Pn\_BUFSTS is 0 and there is no available space in the buffer currently, wait until Pn\_STA.Pn\_BUFSTS becomes 1 or an interrupt due to Pn\_INT\_STA.Pn\_BFRDY\_STA is asserted. When IN is selected as the direction of the bulk PIPE (that is, Pn\_MOD.Pn\_DIR = 1), Pn\_INT\_STA.Pn\_BFRDY\_STA is asserted when the buffer of the PIPE becomes available for new write data.

Therefore, the software can know the timing the buffer of the PIPE prepares new available space by polling Pn\_STA.Pn\_BUFSTS or an interrupt due to Pn\_INT\_STA.Pn\_BFRDY\_STA.

But, Note that Pn\_INT\_STA.Pn\_BFRDY\_STA is not asserted just after a reset (hardware reset, USB\_COM\_CON.PIPE\_CLR, Pn\_CON.Pn\_BCLR and Pn\_CON.Pn\_CLR) and when the software writes the first packet. In that case, since the buffer has available space just after a reset, so the software can write the packet

without being notified on an interrupt due to Pn\_INT\_STA.Pn\_BFRDY\_STA. The software still can see Pn\_STA.Pn\_BUFSTS in that case.

(3) Write bulk IN packet

Write bulk IN packet to be transmitted to the buffer. Bulk IN data is written in a unit of packet and the buffer cannot accept data across the max packet size defined in Pn\_RAMMAP.Pn\_MPKT[10:0].

[writing through Pn\_WRITE register]

a-1) Write data through Pn\_WRITE register. Since only 32-bit access is allowed to the register, data should be written in a unit of 32-bit. The number of write can be calculated as the number of write = the length divided by 4, round-up is required if there is any residue. The written words are concatenated as one packet. When the length of packet is not multiples of 32-bit, the last written word may have unnecessary bytes. The last word should be also written as a 32-bit word. The number of valid bytes in the last word is set in Pn\_CON.Pn\_BYTE\_EN[1:0]. Unnecessary bytes in the last word are discarded.

a-2) Set fields as follows to send the packet. Since only 32-bit access is allowed to Pn\_CON register, all fields below should be set in one word access.

- Pn\_CON.Pn\_SEND = 1
- Pn\_CON.Pn\_BYTE\_EN[1:0] = xxb (the number of valid bytes in last written word)
- In case of the last packet of data group, set Pn\_CON.Pn\_LAST = 1

NOTE

Zero length packet will be sent if Pn\_CON.Pn\_SEND is set to 1 after Pn\_WRITE register is written nothing in the above. In this case, Pn\_CON.Pn\_BYTE\_EN[1:0] is ignored (it's usually set "00" at the same time Pn\_SEND is set).

See **Section 34.6.4.6, Zero Length Packet (ZLP)** about zero length packet.

(4) Are all packets written?

If it is required to send two or more packets, repeat the steps from (2) to (3).

NOTE

When the information of a certain PIPE is read from or write to PIPEn registers, PIPE\_COM.PIPE\_NUM[4:0] should have the index of the PIPE.

## (2) Bulk-OUT Process

The normal Bulk-OUT process is described here. See **Section 34.6.5.5(3), Stream Bulk Process** for Stream bulk process.

In this subsection the process to read bulk OUT packet through Data Interface of EPC or Pn\_READ register is described. DMA transfer as the master function of AXI-IF is available. See **Section 34.6.5.7, DMA Transfer** for the process using DMA transfer.

Figure 34.6-31 Bulk OUT Process Flow

### (1) Change the response mode of the bulk OUT PIPE

Change the response mode of the bulk OUT PIPE to normal response so that the PIPE can receive data.

- Pn\_CON.Pn\_RES\_WEN = 1
- Pn\_CON.Pn\_RES[1:0] = 01b (Normal response)

### (2) Wait for bulk OUT data

When bulk OUT data to the PIPE is received, an interrupt due to Pn\_INT\_STA.Pn\_BFRDY\_STA is asserted. In that case, write 1 to Pn\_INT\_STA.Pn\_BFRDY\_STA to clear.

- Interrupt due to Pn\_INT\_STA.Pn\_BFRDY\_STA asserted
- Check whether Pn\_INT\_STA.Pn\_BFRDY\_STA = 1 or not.
- Pn\_INT\_STA.Pn\_BFRDY\_STA = 1 (clearing the event that OUT data is received at the PIPE)

When receiving OUT data packet, Pn\_STA.Pn\_BUFSTS is also asserted. The meaning of the bit is bulk OUT data packet is ready to be read from Pn\_READ register or through Data Interface of EPC. Polling Pn\_STA.Pn\_BUFSTS is available to know that OUT data packet has been received for the software as well.

### (3) Read bulk OUT packet

Read bulk OUT packet from the buffer. Bulk OUT data is read in a unit of packet and the buffer cannot be read across the max packet size defined in Pn\_RAMMAP.Pn\_MPKT[10:0].

[reading through Pn\_READ register]

a-1) Read Pn\_LNG register in order to know the length of received data

a-2) Read received packet through Pn\_READ register.

Pn\_READ register should be read in a unit of 32-bit. Pn\_READ register is updated and the next 32-bit word of received data is shown in Pn\_READ register every time it is read. The length of received data is known at a-1) and the number of read from Pn\_READ register can be calculated from the length. The number of read = the length divided by 4, round-up is required if there is any residue. If there is residue, it also means the last 32-bit word read has one or more unnecessary bytes. In that case, discard unnecessary bytes.

(4) Are all packets read?

If the bulk OUT PIPE has more packets to be read, repeat the steps from (2) to (3).

Pn\_INT\_STA.Pn\_LSTTR\_STA is asserted when the last packet (short packet or packet with PP = 0) is received.

When a short packet or a packet with PP = 0 (PP is used only in USB3.1) is received, USB3PERI recognizes it is the last packet of the current transfer. It returns ACK with NumP = 0 to host after receiving the packet. ACK with NumP = 0 means that the device cannot receive any more packet currently. The device should send ERDY when it wants to resume the transfer. When the last packet (short packet or packet with PP = 0) has been read to DMAC side and the buffer of the PIPE has available space, USB3PERI automatically send ERDY to request the resume of transfer.

Note that USB3PERI may return ACK with NumP = 0 even when the received packet is not the last packet if it has no available buffer at that time. But when USB3PERI gets available space in the buffer of the PIPE, it automatically sends ERDY to resume the transfer for the PIPE.

#### NOTE

When the information of a certain PIPE is read from or write to PIPEn registers, PIPE\_COM.PIPE\_NUM[4:0] should have the index of the PIPE.

### **(3) Stream Bulk Process**

The process of stream bulk, especially UASP (USB Attached SCSI protocol) application as an example is described here.

#### **(a) PIPE structure of UASP**

UASP assumes 4 pipe model, not including control pipe (PIPE0). The pipes are Command (OUT), Status (IN), Data-in (IN) and Data-out (OUT).

UAS driver sends a command through host stack to Command pipe, device receives it and returns the status or the result for the command from Status pipe. Device receives OUT packet at Data-out pipe or returns IN packet from Data-In pipe, if required.

Stream protocol is used for the parallel operation for commands. Device can receive multiple commands to Command pipe at once. It returns statuses from Status pipe or IN packets from Data-in pipe, or receives OUT packets to Data-out pipe, in “out-of-order” way. Each command has a Stream ID as a tag, and Stream protocol is used for the tagging.

Note Status pipe, Data-in pipe and Data-out pipe are Stream bulk pipes but Command pipe is not. Stream ID is provided in CIU (Command IU) which is received at Command pipe.

**(b) Basic Stream Bulk IN Process**

The basic process of Stream bulk IN is described here.

Stream bulk IN pipe should have Pn\_MOD.Pn\_STREAM = 1 as noted in the first part of **Section 34.6.5.5, Bulk Transfer**.

Figure 34.6-32 Basic Stream Bulk IN Process Flow

(1) Is IN ACK(Prime) received?

IN ACK(Prime) is used to inform device that one or more streams are added to the IN pipe and transfer for it will be started. In case Stream Bulk IN pipe receives IN ACK(Prime), it always responds with NRDY(Prime). Receiving IN ACK(Prime) means the pipe transits to Prime Pipe state of Stream Bulk state machine, and sending NRDY(Prime) means it goes back to Idle state.

USB3PERI automatically changes the setting of Pn\_CON.Pn\_RES[1:0] of the IN pipe to return NRDY (= 00b) and sends NRDY(Prime) to host.

The reception of IN ACK(Prime) is notified on the assertion of Pn\_INT\_STA.Pn\_PRIME\_STA. An interrupt due to it is asserted if enabled.

- Interrupt due to Pn\_INT\_STA.Pn\_PRIME\_STA is asserted, if enabled.
- Check that Pn\_INT\_STA.Pn\_PRIME\_STA = 1

After the confirmation above, clear Pn\_INT\_STA.Pn\_PRIME\_STA.

- Pn\_INT\_STA.Pn\_PRIME\_STA = 1 (Clearing the event that IN ACK(Prime) is received)

Then, the IN pipe is required to prepare to transfer Stream Bulk IN data.

- (2) Is there any Stream ID to be returned?

The data returned from Stream bulk IN pipe should be tagged by Stream ID. The ID is notified in the command from host in advance. In UASP, CIU (Command IU) is sent to Command pipe and the command ID in CIU is used as Stream ID.

If device has received multiple commands, it should decide which command is processed first. In UASP, the operation for Stream is closely related to NCQ (native command queuing) of storage. Stream bulk IN pipe returns data in the order the storage returns.

If there is any Stream ID to be returned, proceed to (3).

- (3) Set Stream ID

Set Stream ID of data which is to be returned next to Pn\_STREAMID.Pn\_STREAM\_N[15:0].

- Pn\_STREAMID.Pn\_STREAM\_N[15:0] = The next stream ID

- (4) Change the response mode of Stream bulk IN pipe

As the IN pipe returned NRDY at (1), so it is in the flow control state. The response mode of the IN pipe was changed to “forced NRDY or NAK response” (= 00b).

Change the response mode of the IN pipe to normal response mode.

- Pn\_CON.Pn\_RES\_WEN = 1
- Pn\_CON.Pn\_RES[1:0] = 01b (Normal response)

- (5) Write Stream bulk IN packet

Write Stream bulk IN packet to be transmitted to the buffer. This step is the same as that for normal bulk IN. Stream bulk IN data is written in a unit of packet and the buffer cannot accept data across the max packet size defined in Pn\_RAMMAP.Pn\_MPKT[10:0].

It is also required to see whether there is available space in the buffer or not on

Pn\_INT\_STA.Pn\_BFRDY\_STA or Pn\_STA.Pn\_BUFSTS. See **Section 34.6.5.5(1), Bulk-IN Process** for details.

[writing through Pn\_WRITE register]

- a-1) Write data through Pn\_WRITE register. Since only 32-bit access is allowed to the register, data should be written in a unit of 32-bit. The number of write can be calculated as the number of write = the length divided by 4, round-up is required if there is any residue. The written words are concatenated as one packet.

When the length of packet is not multiples of 32-bit, the last written word has unnecessary bytes.

The last word should be also written as a 32-bit word. The number of valid bytes in the last word is set in Pn\_CON.Pn\_BYTE\_EN[1:0]. Unnecessary bytes in the last word are discarded.

- a-2) Set fields as follows to send the packet. Since only 32-bit access is allowed to Pn\_CON register, all fields below should be set in one word access.

- Pn\_CON.Pn\_SEND = 1
- Pn\_CON.Pn\_BYTE\_EN[1:0] = xxb (The number of valid bytes in last written word)
- In case of the last packet of data group, set Pn\_CON.Pn\_LAST= 1

## NOTE

Zero length packet will be sent if Pn\_CON.Pn\_SEND is set to 1 after Pn\_WRITE register is written nothing in the above. In this case, Pn\_CON.Pn\_BYTE\_EN[1:0] is ignored (it's usually set "00" at the same time Pn\_SEND is set).

See **Section 34.6.4.6, Zero Length Packet (ZLP)** about zero length packet.

[Using DMA transfer with AXI-IF]

See **Section 34.6.5.7, DMA Transfer** for details.

When the first packet for the Stream ID (= CStream) is written to buffer, USB3PERI returns ERDY(CStream) to host. This means not only the exit from flow control state but the selection of Stream from device. If host agrees the selection, it sends IN ACK(CStream) to start transfer for the Stream ID.

(6) Are all packets written?

If it is required to send two or more packets, repeat the step of (5).

When the last packet for the Stream ID is written, make sure to indicate that on Pn\_CON.Pn\_LAST (in case data is written through Pn\_WRITE register), EPC\_D\_DBWTRANSEND (in case data is transferred through Data Interface of EPC) or Lst bit in PRD table (with AXI-IF).

(7) Is there another Stream ID to be returned?

When the last packet written at (6) is sent to host, EOB (end of burst) bit in it is set to 1 so that it shows the packet is the last one in the burst. Host will send ACK(NumP = 0) as the response to the packet with EOB=1. This means the IN pipe enters flow control state again.

If there is another Stream ID to be returned, repeat the steps from (2) to (6).

Note that USB3PERI might set EOB = 1 in the packet which is not the last one for the Stream ID (= CStream) in case that the preparation of data is delayed and there is no packet in buffer to be sent next to the current packet. In that case, actually EOB is set to 1 in the packet and the IN pipe is considered as being in the flow control state, but no additional operation is required by the software. When the next packet is written in buffer, the IN pipe sends ERDY(CStream) automatically. This means not only the exit from the flow control state but the selection of CStream again. The IN transfer for CStream will be started.

## NOTE

When the information of a certain PIPE is read from or write to PIPEn registers, PIPE\_COM.PIPE\_NUM[4:0] should have the index of the PIPE.

## NOTE

It is possible for host to send ACK(Stream x) and initiates the selection of the Stream. But, basically, to decrease the size of buffer and increase the performance of device, it is desirable that device decides what Stream is processed next seeing its status and initiates the selection of stream. Besides, device cannot send data related to the Stream ID which is not prepared yet. Therefore, USB3PERI responds with NRDY if Stream x is not equal to the Stream ID in Pn\_STREAMID.Pn\_STREAM\_C[15:0]. USB3PERI asserts Pn\_INT\_STA.Pn\_STRMX\_STA in case Stream ID in the received packet is not same as that in Pn\_STREAMID.Pn\_STREAM\_C[15:0], Prime nor NoStream. In that case, the Stream ID requested in the received packet is shown in Pn\_NRDYSTRM register.

It is possible to give priority to the Stream ID requested from host by checking Pn\_NRDYSTRM register, but it is assumed here that device requests another Stream ID which it decided to process.

Especially, READ READY IU and WRITE READY IU are defined to show which stream (command) is processed next from device in UASP. ERDY(Stream) is used in Super Speed Stream Bulk of UASP just as the substitution of them.

Therefore the device initiates the selection of stream in this flow.

**NOTE**

---

From the definition in USB3.1 specification, device which selects the Stream by returning ERDY(Stream) may receive ACK(No Stream) from host. ACK(No Stream) means the rejection from host for proposed Stream ID in ERDY. In such case, device should consider the Stream as “Not Ready”, and may select another Stream.

It depends on the application whether No Stream is really used or not.

---

**(c) Basic Stream Bulk OUT Process**

The basic process of Stream bulk OUT is described here.

Stream bulk OUT pipe should have Pn\_MOD.Pn\_STREAM = 1 as noted in the first part of **Section 34.6.5.5, Bulk Transfer**.

Figure 34.6-33 Basic Stream Bulk OUT Process Flow

(1) Is DP(Prime) received?

DP(Prime) is used to inform device that one or more streams are added to the OUT pipe and transfer for it will be started. In case Stream Bulk OUT pipe receives DP(Prime), it always responds with NRDY(Prime).

Receiving DP(Prime) means the pipe is requested to enter Prime Pipe state of Stream Bulk state machine, and sending NRDY(Prime) means it goes back to Idle state.

USB3PERI automatically changes the setting of Pn\_CON.Pn\_RES[1:0] of the OUT pipe to return NRDY (= 00b) and sends NRDY(Prime) to host.

The reception of DP(Prime) is notified on the assertion of Pn\_INT\_STA.Pn\_PRIME\_STA. An interrupt due to it is asserted if enabled.

- Interrupt due to Pn\_INT\_STA.Pn\_PRIME\_STA is asserted, if enabled.
- Check that Pn\_INT\_STA.Pn\_PRIME\_STA = 1

After the confirmation above, clear Pn\_INT\_STA.Pn\_PRIME\_STA.

- Pn\_INT\_STA.Pn\_PRIME\_STA = 1 (Clearing the event that DP(Prime) is received)

Then, the OUT pipe is required to prepare to transfer Stream Bulk OUT data.

- (2) Is there any Stream ID to be processed

The data received at Stream bulk OUT pipe should be tagged by Stream ID. The ID is notified in the command from host in advance. In UASP, CIU (Command IU) is sent to Command pipe and the command ID in CIU is used as Stream ID.

If device has received multiple commands, it should decide which command is processed. In UASP, the operation for Stream is closely related to NCQ (native command queuing) of storage. Stream bulk OUT pipe processes the stream in the order the storage specifies

If there is any Stream ID to be processed, proceed to (3).

- (3) Set Stream ID

Set Stream ID of the Stream which is processed next to Pn\_STREAMID.Pn\_STREAM\_N[15:0].

- Pn\_STREAMID.Pn\_STREAM\_N[15:0] = The next stream ID

- (4) Change the response mode of Stream bulk OUT pipe

As the OUT pipe returned NRDY at (1), so it is in the flow control state. The response mode of the OUT pipe was changed to “forced NRDY or NAK response” (= 00b).

Change the response mode of the OUT pipe to normal response mode.

- Pn\_CON.Pn\_RES\_WEN = 1
- Pn\_CON.Pn\_RES[1:0] = 01b (Normal response)

After the setting above, ERDY(CStream) is sent from the OUT pipe to host. This means not only the exit from flow control state but the selection of Stream from device. If host agrees the selection, it start the transfer for the stream and sends DP(CStream)

- (5) Wait for bulk OUT data

When bulk OUT data to the OUT PIPE is received, an interrupt due to Pn\_INT\_STA.Pn\_BFRDY\_STA is asserted. In that case, write 1 to Pn\_INT\_STA.Pn\_BFRDY\_STA to clear. This step is the same as that for normal bulk OUT.

- Interrupt due to Pn\_INT\_STA.Pn\_BFRDY\_STA asserted
- Check Pn\_INT\_STA.Pn\_BFRDY\_STA = 1 or not.
- Pn\_INT\_STA.Pn\_BFRDY\_STA = 1 (Clearing the event that OUT data is received at the PIPE)

When receiving OUT data packet, Pn\_STA.Pn\_BUFSTS is also asserted. The meaning of the bit is bulk OUT data packet is ready to be read from Pn\_READ register or through Data Interface of EPC. The software can poll Pn\_STA.Pn\_BUFSTS to know that OUT data packet has been received for the software as well.

- (6) Read bulk OUT packet

Read bulk OUT packet from the buffer. Bulk OUT data is read in a unit of packet and the buffer cannot be read across the max packet size defined in Pn\_RAMMAP.Pn\_MPKT[10:0]. This step is the same as that for normal bulk OUT.

[Reading through Pn\_READ register]

a-1) Read Pn\_LNG.Pn\_LENGTH[15:0] in order to know the length of received data

a-2) Read received packet through Pn\_READ register.

Pn\_READ register should be read in a unit of 32-bit. Pn\_READ register is updated and the next 32-bit word of received data is shown in Pn\_READ register every time it is read. The length of received data is known at a-1) and the number of read from Pn\_READ register can be calculated from the length. The

number of read = the length divided by 4, round-up is required if there is any residue. If there is residue, it also means the last 32-bit word read has one or more unnecessary bytes. In that case, discard unnecessary bytes.

[Using DMA transfer with AXI-IF]

See **Section 34.6.5.7, DMA Transfer** for details.

(7) Are all packets read?

If the bulk OUT PIPE has more packets to be read, repeat the steps from (5) to (6).

Pn\_INT\_STA.Pn\_LSTTR\_STA is asserted when the last packet (short packet or packet with PP = 0) is received.

(8) Is there another Stream ID to be processed?

When the last packet is received at (7), USB3PERI returns ACK with NumP = 0. This means the OUT pipe enters flow control state again.

If there is another Stream ID to be returned, repeat the steps from (2) to (7). Note that Pn\_CON.Pn\_RES[1:0] was changed to 00b (NAK/NRDY response) when the PIPE received the last packet and returned ACK with NumP=0. Pn\_CON.Pn\_RES[1:0] is changed to 01b (normal response) at (4) again, and the PIPE transmits ERDY to resume the transfer.

It is also noted that USB3PERI might return ACK with NumP = 0 for the packet which is not the last one for the Stream ID (= CStream) in case that there is no available space in the buffer for the PIPE currently. In that case, actually NumP is set to 0 in the ACK packet and the OUT pipe is considered as being in the flow control state, but no additional operation is required for the software. When the received packet is transferred to system memory and USB3PERI gets available space in the buffer, the OUT pipe sends ERDY(CStream) automatically. This means not only the exit from the flow control state but the selection of CStream again. The OUT transfer for CStream will be started.

#### NOTE

When the information of a certain PIPE is read from or write to PIPEn registers, PIPE\_COM.PIPE\_NUM[4:0] should have the index of the PIPE.

#### NOTE

It is possible for host to send ACK(Stream x) and initiates the selection of the Stream. But, basically, to decrease the size of buffer and increase the performance of device, it is desirable that device decides what Stream is processed first seeing its status and initiates the selection of stream. Besides, device cannot send for Stream ID which is not available yet. Therefore, USB3PERI responds with NRDY if Stream x is not equal to the Stream ID in Pn\_STREAMID.Pn\_STREAM\_C[15:0]. USB3PERI asserts Pn\_INT\_STA.Pn\_STRMX\_STA in case Stream ID in the received packet is not equal to that in Pn\_STREAMID.Pn\_STREAM\_C[15:0], Prime nor NoStream. In that case, the Stream ID contained in the received packet is shown in Pn\_NRDYSTRM register.

It is possible to give priority to the Stream ID requested from host by checking Pn\_NRDYSTRM register, but it is assumed here that device requests another Stream ID it decided to process.

Especially, READ READY IU and WRITE READY IU are defined to select which stream (command) is processed next from device in UASP. ERDY(Stream) used in super speed Stream Bulk of UASP is alternative of them. So the device initiates the selection of stream in UASP.

**NOTE**

---

From the definition in USB3.1 specification, device selects the Stream by returning ERDY(Stream) may receive ACK(No Stream) from host. ACK(No Stream) means the rejection from host for proposed Stream ID in ERDY. In such case, device should consider the Stream as “Not Ready”, and may select another Stream.

It depends on the application whether No Stream is really used or not.

---

**(4) SuperSpeed UASP Non-Data Transfer**

Figure 34.6-34 Example SuperSpeed UASP Non-Data Transfer

**Figure 34.6-34** shows the part between USB3.1 host and USB3.1 device of Figure 6 in UASP specification Rev.1.0. The example is called as “Non-Data Transfer” but the status PIPE is working as the Stream bulk IN PIPE.

In this case, IN ACK(Stat, Prime) comes to the status PIPE first, then the status PIPE returns NRDY(Stat, Prime).

The some operation is requested on DP(Cmd, CIU) to the command PIPE. The command ID in CIU is used as Stream ID later. When the operation is completed, SIU as the result of the operation is returned from the status PIPE.

Pn\_CON.Pn\_RES[1:0] is set to 01b (normal response) at (4) of **Section 34.6.5.5(3)(b), Basic Stream Bulk IN Process**. When SIU is written to buffer of the status PIPE and it is ready to be transmitted, ERDY(Stat) is sent in order to resume the transfer. IN ACK(Stat) comes to the status PIPE, it sends DP(Stat, SIU) and DP(Stat, SIU) is acknowledged by ACK(Stat).

**(5) SuperSpeed UASP Data-IN transfer**

Figure 34.6-35 Example SuperSpeed UASP Data-IN Transfer

**Figure 34.6-35** shows the part between USB3.1 host and USB3.1 device of Figure 7 in UASP specification Rev.1.0.

In this case, the Data-in PIPE and the status PIPE are working as Stream bulk IN PIPE.

To set each PIPE in Prime Pipe state, IN ACK(Data-in, Prime) and IN ACK(Stat, Prime) comes. Both PIPEs return NRDY(Prime) to them and go back to Idle state.

The bulk IN operation is requested on DP(Cmd, CIU) to the command PIPE. The command ID in CIU is used as Stream ID later.

If Pn\_CON.Pn\_RES[1:0] of the Data-in PIPE is already set to 01b (normal response), the Data-in PIPE sends ERDY(Data-in) when IN data becomes ready to be transmitted from it. The data transfer from the Data-in PIPE is started by receiving IN ACK(Data-in).

All data transfers from Data-in PIPE are completed, SIU is made as the result of the operation.

If Pn\_CON.Pn\_RES[1:0] of the status PIPE is already set to 01b (normal response), the status PIPE sends ERDY(Stat) when SIU is written to buffer and is ready to be transmitted from it. The SIU is sent as DP(Stat, SIU) when IN ACK(Stat) comes.

**(6) SuperSpeed UASP Data-OUT Transfer**

Figure 34.6-36 Example SuperSpeed UASP Data-OUT Transfer

**Figure 34.6-36** shows the part between USB3.1 host and USB3.1 device of Figure 8 in UASP specification Rev.1.0.

In this case, the status PIPE is working as Stream bulk IN PIPE, and the Data-OUT PIPE is working as Stream bulk OUT PIPE.

To set each PIPE in Prime Pipe state, IN ACK(Stat, Prime) and DP(Data-out, Prime) comes. Both PIPEs return NRDY(Prime) to them and go back to Idle state.

The bulk IN operation is requested on DP(Cmd, CIU) to the command PIPE. The command ID in CIU is used as Stream ID later.

When Pn\_CON.Pn\_RES[1:0] of the Data-out PIPE is changed from 00b to 01b (normal response, note that Pn\_CON.Pn\_RES[1:0] is set to 00b once for Stream bulk PIPE when it receives DP(Prime) or ACK(Prime)), the Data-out PIPE sends ERDY(Data-out) if it has available space in buffer. The data transfer to the Data-out PIPE is started.

All data transfers to Data-out PIPE are completed, SIU is made as the result of the operation.

If Pn\_CON.Pn\_RES[1:0] of the status PIPE is already set to 01b (normal response), the status PIPE sends ERDY(Stat) when SIU is written to buffer and is ready to be transmitted from it. The SIU is sent as DP(Stat, SIU) when IN ACK(Stat) comes.

### 34.6.5.6 Interrupt Transfer

Interrupt Transfer process is described here.

PIPEs other than PIPE0 (PIPE0 is used only for control transfer) can be used for interrupt transfer. The settings for interrupt transfer are shown below.

- PIPE\_COM.PIPE\_NUM[4:0] = the index of PIPE used for the current interrupt transfer
- Pn\_MOD.Pn\_EPNUM[3:0] = the endpoint number of the PIPE
- Pn\_MOD.Pn\_TYPE[1:0] = 11b (interrupt transfer)
- Pn\_MOD.Pn\_DIR = the direction of transfer
- Pn\_RAMMAP.Pn\_BASEAD[13:0] = the base address of buffer assigned for the PIPE
- Pn\_RAMMAP.Pn\_RAMIF[1:0] = the index of RAM interface of the PIPE
- Pn\_RAMMAP.Pn\_MPKT[10:0] = the max packet size of the PIPE
- Pn\_RAMMAP.Pn\_RAMAREA = the size of RAM area assigned for the PIPE
- Pn\_CON.Pn\_DATAIF\_EN = whether Data Interface of EPC or AXI-IF is used or not.
- Pn\_CON.Pn\_EN = 1 (the PIPE is enabled)

These settings are done just after Set Configuration is completed and the device enters configured state. But if the device has only single configuration for each PIPE, these settings can be done after the device is turned on.

#### (1) Interrupt IN Transfer

In this subsection it is assumed that interrupt transfer is used to return small data periodically, so the process to write through Pn\_WRITE register is described here.

Figure 34.6-37 Interrupt IN Process Flow

## (1) Is there any data to be transmitted?

Check if there is any data to be transmitted from interrupt IN PIPE.

If not, set `Pn_CON.Pn_RES[1:0] = 00b` so that the PIPE returns `NRDY` or `NAK` for IN request. When `Pn_CON.Pn_RES[1:0]` already has the value, leave it as it is.

- `Pn_CON.Pn_RES_WEN = 1`
- `Pn_CON.Pn_RES[1:0] = 00b` (`NRDY/NAK` response)

If there is, proceed to (2).

## (2) Change the response mode of the interrupt IN PIPE

As it is confirmed that there is data to be transmitted at (1), change the response mode of the interrupt IN PIPE to enable the transmission of a packet.

- `Pn_CON.Pn_RES_WEN = 1`
- `Pn_CON.Pn_RES[1:0] = 01b` (normal response)

## (3) Check if buffer is available

Check if buffer for the interrupt IN PIPE is available before writing interrupt IN packet. `Pn_STA.Pn_BUFSTS` shows if the buffer is available or not.

- Check whether `Pn_STA.Pn_BUFSTS = 1` or not

If `Pn_STA.Pn_BUFSTS` is 0 and there is no available space in the buffer currently, wait until

`Pn_STA.Pn_BUFSTS` becomes 1 or an interrupt due to `Pn_INT_STA.Pn_BFRDY_STA` is asserted. When IN is selected as the direction of the interrupt PIPE (that is, `Pn_MOD.Pn_DIR = 1`), `Pn_INT_STA.Pn_BFRDY_STA` is asserted when the buffer for the PIPE becomes available for new write data.

Therefore, the software can know the timing the buffer of the PIPE prepares new available space by polling `Pn_STA.Pn_BUFSTS` or an interrupt due to `Pn_INT_STA.Pn_BFRDY_STA`.

## (4) Write interrupt IN packet

Write interrupt IN packet to be transmitted to the buffer. Interrupt IN data is written in a unit of packet and the buffer cannot accept data across the max packet size defined in `Pn_RAMMAP.Pn_MPKT[10:0]`.

[writing through `Pn_WRITE` register]

a-1) Write data through `Pn_WRITE` register. Since only 32-bit access is allowed to the register, data should be written in a unit of 32-bit. The number of write can be calculated as the number of write = the length divided by 4, round-up is required if there is any residue. The written words are concatenated as one packet.

When the length of packet is not multiples of 32-bit, the last written word has unnecessary bytes.

The last word should be also written as a 32-bit word. The number of valid bytes in the last word is set in `Pn_CON.Pn_BYTE_EN[1:0]`. Unnecessary bytes in the last word are discarded.

a-2) Set fields as follows to send the packet. Since only 32-bit access is allowed to `Pn_CON` register, all fields below should be set in one word access.

- `Pn_CON.Pn_SEND = 1`
- `Pn_CON.Pn_BYTE_EN[1:0] = xxb` (The number of valid bytes in last written word)
- In case of the last packet of data group, set `Pn_CON.Pn_LAST = 1`.

## NOTE

Zero length packet will be sent if `Pn_CON.Pn_SEND` is set to 1 after `Pn_WRITE` register is written nothing in the above. In this case, `Pn_CON.Pn_BYTE_EN[1:0]` is ignored (it's usually set "00" at the same time `Pn_SEND` is set).

See **Section 34.6.4.6, Zero Length Packet (ZLP)** about zero length packet.

(5) Are all packets written?

If it is required to send two or more packets, repeat the steps from (3) to (4).

NOTE

---

When the information of a certain PIPE is read from or write to PIPEn registers, PIPE\_COM.PIPE\_NUM[4:0] should have the index of the PIPE.

---

### 34.6.5.7 DMA Transfer

#### (1) Settings for DMA Transfer

Data transfer using DMA in AXI-IF is described here.

Figure 34.6-38 Transfer Setting Flow

(1) Initial settings for DMA transfer

Change the DMA transfers suspended to normal operation.

Since AXI-IF uses EPC\_D\_Pn\_DATAEN[30:1] to see if the PIPE is ready for the transfer or not,

Pn\_CON.Pn\_DATAIF\_EN should be enabled.

- AXI\_CON.MST\_WAIT0 = 0
- Pn\_CON.Pn\_DATAIF\_EN = 1

(2) Prepare PRD table

Prepare PRD table in system memory following the format defined in **Section 34.6.3.2, Physical Region Descriptor (PRD) Table**.

(3) Can AXI-IF accept new PRD table?

AXI-IF handles up to 4 PRD tables concurrently. If the number of PRD tables running in AXI-IF is less than 4, new PRD table can be set for AXI-IF. The “PRD table running” means here that PRD table is assigned to one of DMA\_Ch0\_PRD\_ADRx register and DMA\_Ch0\_CONx.PRD\_ENx is enabled for it.

If there is any DMA\_Ch0\_CONx in which PRD\_ENx is disabled (= 0), new transfer can be assigned to it.

If there is no DMA\_Ch0\_CONx with PRD\_ENx = 0, wait for the completion of one of PRD tables running.

## (4) Enable interrupt from AXI-IF

Enable the assertion of an interrupt from AXI-IF if it is disabled, and clear the interrupt status registers. But the status register might have the interrupt status of completed transfer, and it is also possible that the concurrent transfer is finished and set its status in registers just when the software clears them for new transfer. Make sure not to clear statuses of other PIPE or other DMA\_Ch0\_CONx when clearing the status of PIPE and DMA\_Ch0\_CONx to be used. The bits in status register have “write 1 to clear” function, which means it is not cleared when writing 0. Write 1 just to the bit to be cleared.

- DMA\_INT\_STA.Pxx\_DMACHNG\_STA = 1 (The status of the PIPE to be used is cleared)
- AXI\_INT\_STA.PRDENx\_CLR\_STA = 1 (The status of DMA\_Ch0\_CONx to be used is cleared)
- AXI\_INT\_STA.PRDERRO\_x\_STA = 1 (The error status of DMA\_Ch0\_CONx to be used is cleared)

After clearing the interrupt status, enable the interrupt for the PIPE and DMA\_Ch0\_CONx to be used.

- AXI\_INT\_ENA.DMA\_INT\_ENA = 1
- AXI\_INT\_ENA.PRDENx\_CLR\_ENA = 1
- AXI\_INT\_ENA.PRDERRO\_x\_STA = 1

## (5) Set the address of PRD table

Set the address of PRD table generated at (2) in DMA\_Ch0\_PRD\_ADRx register. If the transfer consists of some PRD tables, set the address of the first PRD table.

- DMA\_Ch0\_PRD\_ADRx = the address of PRD table

## (6) Enable PRD table

Set the information of PRD table to DMA\_Ch0\_CONx register, and enable it on DMA\_CH0\_CONx.PRD\_ENx. The fields below can be set in one word access.

- DMA\_CH0\_CONx.PIPE\_DIRx = the direction of the PIPE
- DMA\_CH0\_CONx.PIPE\_NOx = the index of the PIPE
- DMA\_CH0\_CONx.PRD\_ENx = 1

In case the transfer of new PRD table is expected to wait for the completion of one of the concurrent transfer and be executed after it, use DMA\_CH0\_CONx.EXTPRD\_ENx. See **Section 34.6.4.4, AXI DMA Transfer Control** for details of DMA\_CH0\_CONx.EXTPRD\_ENx.

• DMA\_CH0\_CONx.EXTPRD\_NOx = the index of DMA\_CH0\_CONy which completion of transfer new PRD table is waiting for.

- DMA\_CH0\_CONx.EXTPRD\_ENx = 1 (the use of EXTPRD\_EN is enabled)

Note that EXTPRD\_ENx is not cleared if PRD\_ENy of DMA\_CH0\_CONy which completion is waited for is already 0. That is, EXTPRD\_ENx cannot be used for DMA\_CH0\_CONy which has already cleared its enable bit (PRD\_ENy). Make sure that PRD\_ENy is still 1 and the related transfer is still being executed when EXTPRD\_EN is associated. When PRD\_ENy is already cleared to 0, do not use EXTPRD\_EN. In that case, there is no need to wait for the completion of DMA\_CH0\_CONy since it has already been finished.

## (2) Transfer Stop Process

Process to stop PRD Table that has Transfer process enabled is described in this section.

Figure 34.6-39 Transfer Stop Flow

### (1) Disable PRD\_EN

Set PRD Table to have Transfer Process suspended to “Stop DMA Transfer.”

Below is for the case to stop Transfer with PRD Table that was set in DMA\_CH0\_CONx

- DMA\_CH0\_CONx.PRД\_ENx = 0b (Set to Stop DMA Transfer)

### (2) Data transfer stop check

Wait the Transfer with the PRD Table that was requested to be stopped in (1) is stopped completely.

Number of PIPE being transferred can be checked by referencing a register provided below. Wait for the applicable status is cleared in case the register indicates Transfer in progress at the PIPE stop was requested in (1) Transfer.

- AXI\_STA.DMA\_TRANS0 = 0b (Stand-by)

or

- AXI\_STA.DMA\_PIPE0 = xxh (Other PIPEs than requested for stop shall be selected.)

Setting for PRD Table can be rewritten after it is confirmed that the applicable PRD Table is not in use.

### 34.6.5.8 Power Management

#### (1) Suspend in USB3.1 (Transition of State from U0 to U3)

The process to transit to U3 state of LTSSM in USB3.1 specification is described here.

Figure 34.6-40 Suspend in USB3.1 Flow

##### (1) Transition to U3 is informed

It is defined that only a downstream port (host or hub) can initiate U3 entry and an upstream port cannot reject it in USB3.1 specification. The downstream port initiates U3 entry by sending LGO\_U3.

When EPC receives LGO\_U3, it accepts it and executes the transition to U3 inside. At this time, USB\_INT\_STA\_1.B3\_LNKCNG\_STA is asserted since the change of the link status occurs. The current status of LTSSM can be known by seeing PORTSC.PLS[3:0].

Check whether the transition to U3 is requested or not when LTSSM is in U0 state and

USB\_INT\_STA\_1.B3\_LNKCNG\_STA is asserted. If LTSSM has changed to U3 state, the transition to U3 has been requested from downstream port.

- Interrupt due to USB\_INT\_STA\_1.B3\_LNKCNG\_STA is generated
- Check whether PORTSC.PLS[3:0] shows U3 or not.

Note that there is another possibility that a disconnection or error occurs as the factor of the change of the link status. In such case, follow the flows noted in other sections.

After confirming the factor of the change, clear USB\_INT\_STA\_1.B3\_LNKCNG\_STA. Then, proceed to (2).

- USB\_INT\_STA\_1.B3\_LNKCNG\_STA = 1 (Clearing the event that the link has changed)

(2) Is stopping USB3.1-PHY clock required?

LTSSM in EPC has transited to U3 at (1), but USB3.1-PHY is in P0 or P2 state of USB3.1-PHY state since only P0 or P2 can be selected as the setting of USB30\_CON.U3\_POW\_SEL[1:0]. Note the difference between U0/U1/U2/U3 and P0/P1/P2/P3. Ux is the power management states in LTSSM. Px is the power management states for USB3.1-PHY and the upper layer. USB30\_CON.U3\_POW\_SEL[1:0] defines the PHY state in which USB3.1-PHY is placed when the transition to U3 is requested in LTSSM. P3 is defined as the state in which the clock is suspended. The reason why P3 is not selected as the setting of USB30\_CON.U3\_POW\_SEL[1:0] is that it may cause issues if the clock from USB3.1-PHY is stopped suddenly.

If USB3.1-PHY is not required to be placed in P3 when the upper layer is in U3 state, no additional operation is required here. If it is required, proceed to (3).

(3) Is USB3.1-PHY placed in P2?

As noted above, P0 or P2 can be selected as USB3.1-PHY state on USB30\_CON.U3\_POW\_SEL[1:0] when LTSSM of upper layer enters U3. If USB3.1-PHY is in P2 at present and expected to enter P3, it should be move to P0 once before it is operated to enter P3.

- USB30\_CON.POW\_SEL\_WEN = 1
- USB30\_CON.POW\_SEL[2:0] = 110b (the transition from P2 to P0 is requested when LTSSM is in U3)

When the transition to P0 requested has been done, an interrupt due to the transition is asserted. Since there is no reason to fail in the transition, so USB3.1-PHY surely enters P0, but confirm the result of the transition.

- Interrupt due to the transition asserted
- Check whether USB\_INT\_STA\_1.B3\_PSSUCS\_STA is asserted or not. If it is asserted, the transition has been done successfully. Clear it after the confirmation.
- If USB\_INT\_STA\_1.B3\_PSSUCS\_STA is not asserted, check whether USB\_INT\_STA\_1.B3\_PSFALL\_STA is asserted or not. If it is asserted, the presumed factors are explained at (5).

If USB30\_CON.U3\_POW\_SEL[1:0] = 00b (P0) and USB3.1-PHY is placed in P0 when LTSSM enters U3, this operation is not required.

Hence, USB3.1-PHY is P0 at present.

(4) Operation to move USB3.1-PHY to P3

Set USB30\_CON.POWSEL[2:0] to place USB3.1-PHY in P3.

- USB30\_CON.POW\_SEL\_WEN = 1
- USB30\_CON.POWSEL[2:0] = 101b (the transition from P0 to P3 is requested when LTSSM is in U3)

When the transition to P3 requested has been done, an interrupt due to the transition is asserted. Since there is no reason to fail in the transition, so USB3.1-PHY surely enters P3, but confirm the result of the transition.

- Interrupt due to the transition asserted
- Check whether USB\_INT\_STA\_1.B3\_PSSUCS\_STA is asserted or not. If it is asserted, the transition has been done successfully. Clear it after the confirmation.
- If USB\_INT\_STA\_1.B3\_PSSUCS\_STA is not asserted, check whether USB\_INT\_STA\_1.B3\_PSFALL\_STA is asserted or not. If it is asserted, the presumed factors are explained at (5).

(5) Check the factors for failure result

If case the transition of power state noted here failed, the presumed factors are as follows.

- (1) the disconnection has occurred and LTSSM transits to SS.Disabled.
- (2) U3Wakeup LFPS from host has come and LTSSM has started the transition to U0.
- (3) the warm reset from host has come

See the statuses below to know whether the factors above occur or not.

- USB\_INT\_STA\_1.B3\_DISABLE\_STA = 1 (if (1) occurred)
- PORTSC.PLS[3:0] = 0h (if (2) occurred )
- USB\_INT\_STA\_1.B3\_WRMIRST\_STA = 1 (if (3) occurred)

If (1) occurs, see **Section 34.6.5.3(3), USB Disconnection** for the disconnection process.

If (2) occurs, see **Section 34.6.5.3(2), USB Connection** for the resume process from U3.

If (3) occurs, see **Section 34.6.5.3(4), Warm Reset Process** for the warm reset process.

In case the transition of power state failed but the factors above has not caused it, fatal error might occur in the system.

## (2) Resume in USB3.1 (from U3 to U0: Initiated by Host)

The process for the transition to U0 initiated by host in USB3.1 is described here.

Figure 34.6-41 Resume in USB3.1 (Host Initiated) Flow

### (1) Does the transition to U0 occur?

In case EPC is in U3 and receives U3Wakeup LFPS from host, it automatically responds to the LFPS and go back to U0. At this time, USB3.1-PHY is moved back to P0 as well.

The event is notified on the assertion of USB\_INT\_STA\_1.B3\_LNKCNG\_STA. An interrupt due to the bit is asserted if enabled.

- Interrupt due to USB\_INT\_STA\_1.B3\_LNKCNG\_STA is asserted, if enabled
- Check that USB\_INT\_STA\_1.B3\_LNKCNG\_STA = 1
- Check that PORTSC.PLS[3:0] shows U0 (= 0h)

After the confirmation above, clear USB\_INT\_STA\_1.B3\_LNKCNG\_STA.

- USB\_INT\_STA\_1.B3\_LNKCNG\_STA = 1 (clearing the event of the link change)

If USB3.1-PHY is placed in P3 following the flow in **Section 34.6.5.8(1), Suspend in USB3.1 (Transition of State from U0 to U3)** and the clock from it is stopped in U3, the clock is also resumed as USB3.1-PHY goes back to P0. USB\_INT\_STA\_1.B3\_PLLWKUP\_STA is asserted in that case. If it is asserted, clear it.

- USB\_INT\_STA\_1.B3\_PLLWKUP\_STA = 1 (clearing the event of USB3.1 PLL Wakeup)

### (3) Resume in USB3.1 (from U3 to U0: Initiated by Device)

The process for the transition to U0 initiated by device in USB3.1 is described here.

Figure 34.6-42 Resume in USB3.1 (Device Initiated) Flow

#### (1) Is USB3.1-PHY in P3?

If USB3.1-PHY is placed in P3 following the flow in **Section 34.6.5.8(1), Suspend in USB3.1 (Transition of State from U0 to U3)** and the clock from it is stopped in U3, it is required to wake up USB3.1-PHY since the clock from USB3.1-PHY should be provided for the operations here.

See **Section 34.6.5.8(6), USB3.1-PHY (PLL) Wakeup Process** for the process of wakeup of USB3.1-PHY.

If USB3.1-PHY is P0 or P2 and the clock from it is being provided, it is not required to wake up USB3.1-PHY.

#### (2) Request the transition to U0

Request the transition to U0 in LTSSM as follows.

- PORTSC.LWS = 1
- PORTSC.PLS[3:0] = 0h (U0 state is requested)

#### (3) Does the transition to U0 occur?

With the request to transit to U0, EPC asserts U3Wakeup LFPS to host. When host responds to the LFPS and LFPS handshake is established, EPC has transitioned to U0.

At that time, USB\_INT\_STA\_1.B3\_LNKCNG\_STA is asserted and an interrupt due to it is caused if enabled.

- Interrupt due to USB\_INT\_STA\_1.B3\_LNKCNG\_STA is asserted, if enabled
- Check that USB\_INT\_STA\_1.B3\_LNKCNG\_STA = 1
- Check that PORTSC.PLS[3:0] shows U0 (= 0h)

After the confirmation above, clear USB\_INT\_STA\_1.B3\_LNKCNG\_STA.

- USB\_INT\_STA\_1.B3\_LNKCNG\_STA = 1 (Clearing the event of the link change)

#### (4) Function Suspend

The process for function suspend in USB3.1 is described here.

The function suspend is defined for SuperSpeed device and functions are placed into function suspend on the reception of Set Feature(FUNCTION\_SUSPEND). Since function has one or more interfaces, what function is selected to be suspend is recognized by seeing what interface receives the request. If the function has multiple interfaces, the request comes to the first interface of the function.

Note that the specification defines about the function suspend as follows.

- A function may be placed into function suspend independently of other functions within the device.
- A device may be transitioned into device suspend regardless of the function suspend state of any function within the device.
- Function suspend state is retained while in device suspend and throughout the device suspend entry and exit processes.

The definition of function depends on the specification of device.

Figure 34.6-43 Function Suspend Process

(1) Set Feature(FUNCTION\_SUSPEND) is received

In case Set Feature(FUNCTION\_SUSPEND) comes, the function suspend is requested. The function suspend is requested only via Set Feature(FUNCTION\_SUSPEND).

(2) See what function is selected

See what function within the device is selected. The interface number of the function is specified in the lower byte of wIndex. If the function has multiple interfaces, the lower byte of wIndex shall be the first interface of the function.

Bit 0 in the upper byte of wIndex shows which of normal state (= 0) or suspended state (= 1) is requested. When bit 0 is 1 and the function has been enabled, the selected function is requested to suspend. When bit 0 is 0 and the function has been suspended, the selected function is requested to exit from suspended state.

Bit 1 in the upper byte for wIndex shows whether the function remote wakeup is enabled or not.

(3) Suspend the selected function

Suspend the function which is selected at (2).

If the function cannot be suspended, the device may be allowed to return STALL response to Set Feature(FUNCTION\_SUSPEND).

## (5) Function Remote Wakeup

The process of function remote wakeup is described here.

The function remote wakeup is defined for SS device and `DEVICE_REMOTE_WAKEUP` is not supported by SuperSpeed device.

As a function may be suspended independently of other functions, the link is still in U0 state even when one or more functions are suspended. In case the suspended function within the device requires to be woken up and the link is U0 state, the device simply sends Function Remote Wakeup Notification. In case the function is requesting the remote wake up but the link is in the low power state (U1, U2 or U3), resume the link to U0 state first and then sends Function Remote Wakeup Notification.

The function shows whether it supports the function remote wakeup or not in the response to Get Status from the interface which belongs to the function.

It is also required that Function Remote Wake is enabled to request the function remote wakeup from the device. Function Remote Wake is disabled (= 0) in the default state and set when Set Feature(FUNCTION\_SUSPEND) is received and bit 1 of the upper byte of wIndex in setup data is 1. The current status of Function Remote Wake is shown in the response to GetStatus from the interface which belongs to the function.

Figure 34.6-44 Function Remote Wakeup Process

(1) Is Function Remote Wake supported?

If the function within the device does not support Function Remote Wake, it cannot request the function remote wakeup. The function shows whether it supports Function Remote Wake or not in the response to Get Status from the interface which belongs to the function. See **Section 34.6.5.9(5), Get Status** for details.

(2) Is Function Remote Wake enabled?

If Function Remote Wake is disabled for the function within the device, it cannot request the function remote wakeup. The current status of Function Remote Wake is shown in the response to Get Status from the interface which belongs to the function. See **Section 34.6.5.9(5), Get Status** for details.

(3) The link is in U0 state?

To send Function Remote Wake Notification, the link is required to be in U0 state.

If USB3PERI is in U1 or U2 state, it automatically goes back to U0 state when Notification written in USB3\_TP\_DAT\_x register is sent. Therefore, the software need not mind the link status except the case the link is U3. Proceed to (4).

If USB3PERI is in U3 state, it is required to exit from the state first. See **Section 34.6.5.8(3), Resume in USB3.1 (from U3 to U0: Initiated by Device)** for the process of resume in USB3.1.

(4) Send Function Remote Wake Notification

If the link is in U0 state, then send Function Remote Wake Notification.

- Write Function Remote Wake Notification to USB3\_TPDAT\_x registers
- USB30\_CON.B3\_TP\_SEND = 1 (Notification in USB3\_TPDAT\_x registers is sent)

(5) Is the device accessed?

If tNotification ( = 2500 ms) has passed and the device has not been accessed yet from the time Function Remote Wake Notification was sent, it is required to send Function Remote Wake Notification again. The device should send the notification until the function is resumed.

When Set Feature(FUNCTION\_SUSPEND) with bit 0 = 1 in the upper byte of wIndex comes, the function is resumed.

## (6) USB3.1-PHY (PLL) Wakeup Process

The process to wake up USB3.1-PHY (PLL) in case it is suspended is described here.

Figure 34.6-45 USB3.1-PHY (PLL) Wakeup Process Flow

### (1) Set USB3.1-PHY wakeup request

There are 2 ways to request USB3.1-PHY to wake up.

The first way is to set USB30\_CON.B3\_PLLWAKE.

[In case register is used]

- USB30\_CON.B3\_PLLWAKE = 1

### (2) Is USB3.1-PHY (PLL) enabled?

Responding to the wake up request at (1), USB3.1-PHY (PLL) becomes enabled.

At that time, USB\_INT\_STA\_1.B3\_PLLWKUP\_STA is asserted and an interrupt due to it is generated if enabled.

- Interrupt due to USB\_INT\_STA\_1.B3\_PLLWKUP\_STA is generated
- Check that USB\_INT\_STA\_1.B3\_PLLWKUP\_STA = 1

After the confirmation above, clear USB\_INT\_STA\_1.B3\_PLLWKUP\_STA.

- USB\_INT\_STA\_1.B3\_PLLWKUP\_STA = 1 (Clearing the event of USB3.1 PLL Wakeup)

### (3) Clear USB3.1-PHY wakeup request

After the resume of USB3.1-PHY is confirmed at (2), clear USB3.1-PHY wakeup request set in (1).

[In case register is used]

- USB30\_CON.B3\_PLLWAKE = 0

[In case input signal is used]

- B3\_PLL\_WAKEIN = 0

## (7) Suspend in USB2.0

The process when the state transition to suspend in USB2.0 occurs is described here.

Figure 34.6-46 Suspend in USB2.0 Process Flow

### (1) Does the transition to suspend occur?

In USB2.0 (HS/FS) host requests device to make a transition to suspended state by sending no signal to it for a certain period. Device transits to suspended state when it detects constant idle state on USB bus for more than 3.0 ms.

When EPC works as HS or FS device and finds constant idle state on USB bus and make the transition to suspended state, it asserts USB\_INT\_STA\_1.B2\_SPND\_STA. An interrupt due to it is generated if enabled.

- Interrupt due to USB\_INT\_STA\_1.B2\_SPND\_STA is generated, if enabled
- Check whether USB\_INT\_STA\_1.B2\_SPND\_STA = 1 or not.

After the confirmation above, clear USB\_INT\_STA\_1.B2\_SPND\_STA.

- USB\_INT\_STA\_1.B2\_SPND\_STA = 1 (Clearing the event of entering USB2.0 suspension)

### (2) Is stopping USB2.0-PHY clock required?

PLL in USB2.0-PHY is still running even when EPC enters the suspended state of USB2.0. In order to stop PLL in USB2.0-PHY, set USB20\_CON.B2\_SUSPEND

- USB20\_CON.B2\_SUSPEND = 1 (Clock from USB2.0-PHY is stopped)

If it is not required to stop the clock from USB2.0-PHY, no operation is needed here.

**(8) Resume in USB2.0 (Initiated by Host)**

The process to resume in USB2.0 initiated by host is described here.

Figure 34.6-47 Resume in USB2.0 (Initiated by Host) Process Flow

(1) Does the resume in USB2.0 occur?

In case EPC is in suspended state and receives the resume signal from host, it responds to it and exits from the suspended state automatically.

At that time EPC asserts USB\_INT\_STA\_1.B2\_RSUM\_STA or USB\_INT\_STA\_1.B2\_L1RSUM\_STA depending on the low power state it stayed in. An interrupt due to them is generated if enabled.

- Interrupt due to USB\_INT\_STA\_1.B2\_RSUM\_STA or USB\_INT\_STA\_1.B2\_L1RSUM\_STA is generated, if enabled.
- Check whether USB\_INT\_STA\_1.B2\_RSUM\_STA or USB\_INT\_STA\_1.B2\_L1RSUM\_STA = 1 or not.

After the confirmation above, clear the status bit asserted.

- USB\_INT\_STA\_1.B2\_RSUM\_STA = 1 (In case of resume from suspend)
- USB\_INT\_STA\_1.B2\_L1RSUM\_STA = 1 (In case of resume from sleep)

If USB2.0 PLL is stopped in the suspend state, it is also resumed when EPC exits from the suspend state.

### (9) Resume in USB2.0 (Initiated by Device)

The process to resume in USB2.0 initiated by device is described here.

Figure 34.6-48 Resume in USB2.0 (Initiated by Device) Process Flow

(1) Is the clock from USB2.0-PHY stopped?

If the clock from USB2.0-PHY is stopped following the flow in **Section 34.6.5.8(7), Suspend in USB2.0**, it is required to wake up USB2.0-PHY since the clock from USB2.0-PHY should be provided for the operations here.

See **Section 34.6.5.8(10), USB2.0 PHY (PLL) Wakeup Process** for the process to wakeup of USB2.0-PHY.

(2) Request the exit from the suspended state

Request to exit from the suspended state by setting as follows.

- USB20\_CON.B2\_RSUM\_IN = 1 (resume request)

If PLL in USB2.0-PHY is not stopped in suspended state, that is, if USB20\_CON.B2\_SUSPEND is not set to 1 in suspended state, USB\_INT\_STA\_1.B2\_RSUM\_STA or USB\_INT\_STA\_1.B2\_L1RSUM\_STA may be asserted when downstream port responds to the resume request and bus activity comes back.

But, if it is stopped, they are not asserted here because they are asserted when USB20\_CON.B2\_SUSPEND is cleared so they would have already been asserted at (1).

In either case host should responds to the resume request from the device and bus becomes active again, so the device is required only to wait for the resume of transfer.

**(10) USB2.0 PHY (PLL) Wakeup Process**

Figure 34.6-49 USB2.0-PHY (PLL) Wakeup Process Flow

**(1) Set USB2.0-PHY wakeup request**

There are 2 ways to request USB2.0-PHY to wake up.

The first way is to clear USB20\_CON.B2\_SUSPEND.

[In case register is used]

- USB20\_CON.B2\_SUSPEND = 0 (Clearing the value set in **Section 34.6.5.8(7), Suspend in USB2.0**)

**(2) Is USB2.0-PHY (PLL) enabled?**

Responding to the wake up request at (1), USB2.0-PHY (PLL) becomes enabled.

At that time, USB\_INT\_STA\_1.B2\_RSUM\_STA is generated and an interrupt due to it is caused if enabled.

- Interrupt due to USB\_INT\_STA\_1.B2\_RSUM\_STA is generated
- Check that USB\_INT\_STA\_1.B2\_RSUM\_STA = 1

After the confirmation above, clear USB\_INT\_STA\_1.B2\_RSUM\_STA.

- USB\_INT\_STA\_1.B2\_RSUM\_STA = 1 (Clearing the event of USB2.0 PLL Wakeup)

If USB3PERI was in L1 state, USB\_INT\_STA\_1.B2\_L1RSUM\_STA is asserted instead.

**(3) Clear USB2.0-PHY wakeup request**

After the resume of USB2.0-PHY is confirmed at (2), clear B2\_PLL\_WAKEIN input signal if used.

If USB20\_CON.B2\_SUSPEND is used to place USB2.0-PHY in suspended state, USB20\_CON.B2\_SUSPEND is automatically cleared.

[In case input signal is used]

- B2\_PLL\_WAKEIN = 0

### (11) Process of Transition from U0 to U1/U2 in USB3.1 (Initiated by Device)

With the settings as follows, USB3PERI automatically controls the transition from U0 to U1/U2 by sending LGO\_U1/LGO\_U2 request or by responding to LGO\_U1/LGO\_U2 request from host.

- PORTPMSC.U1\_TIMEOUT[15:0] = U1 timeout value defined by user
- PORTPMSC.U2\_TIMEOUT[15:0] = U2 timeout value in received U2 Inactivity Timeout LMP
- SSIFCMD.SSIF\_URES[1:0] = 00b (LAU responses to LGO\_U1/LGO\_U2 are allowed)
- SSIFCMD.SSIF\_UREQ[1:0] = 00b (sending LGO\_U1/LGO\_U2 by timeout is allowed)

USB3PERI controls the exit from U1/U2 state when it has any available data to be transmitted in buffer or when host requests wakeup as well. No additional operation by the software is required for the cases.

But there might be a case the software requests the transition to U1/U2 state at any point it wants. The process for such case is described here. But note that U1 timeout value can be defined by user, so consider it first to change the value of PORTPMSC.U1\_TIMEOUT[15:0] in case LGO\_U1 is required to be sent.

The process of Sleep (U1/U2) transition in USB3.1 when the device initiates at any timing is explained. This process flow is for usage when the device initiates LGO\_U1/LGO\_U2 at any time, and the timer which determine the duration for no data on the bus may be set in PORTPMSC.U1\_TIMEOUT. The device can issue LGO\_U1 after the timeout of the timer.

Figure 34.6-50 Transition to U1/U2 (Initiated by Device) Process Flow

#### (1) Wait for 500 ms

In C.3.2.2 and C.3.2.3 of USB3.1 specification, it is defined that the link should be kept in U0 after device has sent ERDY until host sends a request in response to the ERDY or until tERDYtimeout ( = 500 ms) occurs.

Since USB3PERI sends ERDY automatically depending on the status of buffer, so it might be difficult to know when it has sent ERDY exactly.

If the software does not assure when the last ERDY has been sent, wait for 500 ms from the point. If no response from host comes, it can request the transition to U1/U2 state. Note that USB3PERI might send ERDY again depending on the process of transfer if the response from host comes before the timeout.

If the software assures when the last ERDY has been sent and 500 ms has passed, it can request the transition to U1/U2 immediately. The triggers to send ERDY for USB3PERI are :

- 1) IN packet is written to buffer
- 2) Pn\_CON.Pn\_RES[1:0] is changed to normal response (= 01b)
- 3) Buffer for OUT endpoint was full once but becomes available

- 4) Buffer for OUT endpoint had the last packet of transfer (short packet or packet with PP = 0) but it has been transferred to system memory.

If these triggers has not occurred for 500 ms, it can be said that 500 ms has passed at least from the last ERDY the device has sent.

(2) Set PORTSC.PLS[3:0]

The software can request the transition to U1 or U2 by setting PORTSC.PLS[3:0]. It is also required to set SSIFCMD.SSIF\_UDIR[1:0] to enable the function.

- SSIFCMD.SSIF\_UDIR[1:0] = 00b (If only one of LGO\_U1 or LGO\_U2 is requested, unused bit does not require to be enabled.)
- PORTSC.PLS[3:0] = 1h (If the transition to U1 is requested)  
2h (If the transition to U2 is requested)

With the operations above, USB3PERI sends LGO\_U1 or LGO\_U2 to request the transition to U1 or U2. If host accepts it, the link makes a transition to the low power state.

When LTSSM in USB3PERI enters U1 or U2, USB\_INT\_STA\_1.B3\_LNKCNG\_STA is asserted. An interrupt due to it is generated if enabled. PORTSC.PLS[3:0] shows the current state of LTSSM.

- Interrupt due to USB\_INT\_STA\_1.B3\_LNKCNG\_STA is asserted
- Check that USB\_INT\_STA\_1.B3\_LNKCNG\_STA = 1
- Check that PORTSC.PLS[3:0] shows the requested state (U1 or U2).

Note that PORTSC.PLS[3:0] might show another state if the link transits to U1/U2 but host requests the exit from the state soon.

If host does not accept the request, USB\_INT\_STA\_1.B3\_LNKCNG\_STA is not asserted. In case the software cannot detect the assertion of the bit even when it waits for a certain time, it should consider the possibility that host rejected the request. The software can send the same request again, but host might intend new transfer, so the software had better the state of USB3PERI in U0 for the moment.

After the confirmation above, write 1 to USB\_INT\_STA\_1.B3\_LNKCNG\_STA to clear.

- USB\_INT\_STA\_1.B3\_LNKCNG\_STA = 1 (Clearing the event that the link status is changed)

### 34.6.5.9 Device Requests

This section describes the operations required for USB device requests.

#### (1) Clear Feature

This request is used to clear or disable a specific feature.

In case the recipient is device and the device works in SS, U1\_ENABLE, U2\_ENABLE, LTM\_ENABLE and B3\_NTF\_HOST\_REL are defined as feature selectors. But as B3\_NTF\_HOST\_REL is defined for OTG, it is not used for device.

- (a) When Clear Feature(U1\_ENABLE) comes, disable the initiation of U1 entry of USB3PERI as follows. Note that U1\_ENABLE enables or disables only the initiation of U1 entry but the device is still allowed to accept LGO\_U1 from downstream port and enters U1 state regardless of the feature.
  - SSIFCMD.SSIF\_UDIR[0] = 1 (The initiation of LGO\_U1 due to direct request is disabled.)
  - SSIFCMD.SSIF\_UREQ[0] = 1 (The initiation of LGO\_U1 due to timeout is disabled.)
- (b) When Clear Feature(U2\_ENABLE) comes, disable the initiation of U2 entry of USB3PERI as follows. Note that U2\_ENABLE enables or disables only the initiation of U2 entry but the device is still allowed to accept LGO\_U2 from downstream port and enters U2 state regardless of the feature.
  - SSIFCMD.SSIF\_UDIR[1] = 1 (The initiation of LGO\_U2 due to direct request is disabled.)
  - SSIFCMD.SSIF\_UREQ[1] = 1 (The initiation of LGO\_U2 due to timeout is disabled.)
- (c) When Clear Feature(LTM\_ENABLE) comes, disable the transmission of LTM (Latency Tolerance Message). Note that SS device must support U1 and U2 features, but LTM feature is optional. SS device shows whether it supports LTM feature or not on LTM capable bit in SuperSpeed USB Device Capabilities Descriptor.

In case the recipient is device and the device works in HS or FS, DEVICE\_REMOTE\_WAKEUP and TEST\_MODE are defined as feature selectors.

- (d) When Clear Feature(DEVICE\_REMOTE\_WAKEUP) comes, disable the remote wakeup function of the device.
- (e) When TEST\_MODE feature is enabled, the device is in test mode. But it is defined that the power cycle is used for the device to exit from test mode and Clear Feature(TEST\_MODE) does not clear the feature.

For FUNCTION\_SUSPEND, Clear Feature is not used to change the feature. Only Set Feature(FUNCTION\_SUSPEND) is used to change the feature.

In case the recipient is endpoint, ENDPOINT\_HALT is defined as feature selector. All of SS, HS and FS devices support the feature.

- (f) When Clear Feature(ENDPOINT\_HALT) comes, it means the reset of Halt feature and the initialization of the endpoint.

At first, set Pn\_CON.Pn\_CLR and wait for Pn\_CON.Pn\_CLR to return to 0.

- Pn\_CON.Pn\_CLR = 1 (Initialization of the endpoint (pipe) is required.)
- Wait for Pn\_CON.Pn\_CLR = 0

After Pn\_CON.Pn\_CLR = 0, set enable bits below again.

- Pn\_CON.Pn\_EN = 1 (The endpoint (pipe) is enabled)
- In case of DMA Transfer, Pn\_CON.Pn\_DATAIF\_EN = 1 (EPC\_D\_Pn\_DATAEN[30:1] is enabled for the endpoint)

Then, set Pn\_CON.Pn\_RES[1:0] = 01b so that the endpoint responds in normal state.

- Pn\_CON.Pn\_RES[1:0] = 01b (Normal response)

It is not recommended that the endpoint 0 (PIPE0) supports function STALL for HS and FS device. It is also defined that SS device does not support the feature. If the device does not support Halt feature for the endpoint 0, it executes the control transfer of Clear Feature(ENDPOINT\_HALT) for the endpoint 0 normally but can ignore the request.

It is noted in **Section 34.6.5.9(5), Get Status** how each feature is controlled as the status of the device.

## (2) Get Configuration

This request returns the current device configuration value.

In case this request is received, return the current configuration value. It has been selected with Set Configuration. If not, return the initial value (= zero).

## (3) Get Descriptor

This request returns the specified descriptor if the descriptor exists.

The length of transfer is specified in wLength of setup data. In case the size of the descriptor equals to or is smaller than the value in wLength, transmit all of the descriptor from the beginning to the end. In case the size of the descriptor is larger than the value in wLength, transmit a part of the descriptor from the beginning to the length specified in wLength.

Each packet transporting the descriptor should equal to or smaller than the max packet size defined for each speed mode (512byte for SS, 64byte for HS and 8/16/32/64byte for FS). If the size of the last packet equals to the max packet size defined, zero length packet should follow it.

## (4) Get Interface

This request returns the selected alternate setting of the specified interface.

In case this request is received, return the current alternate setting of the interface. It has been selected with Set Interface. If not, return the initial value (= zero).

**(5) Get Status**

This request returns status for the specified recipient.

In case the recipient is device, the information returned for this request as SuperSpeed device is shown in **Figure 34.6-51**.

| D7                          | D6  | D5  | D4         | D3        | D2        | D1               | D0               |
|-----------------------------|-----|-----|------------|-----------|-----------|------------------|------------------|
| Reserved<br>(Reset to Zero) |     |     | LTM Enable | U2 Enable | U1 Enable | Remote<br>Wakeup | Self-<br>Powered |
| D15                         | D14 | D13 | D12        | D11       | D10       | D9               | D8               |
| Reserved (Reset to Zero)    |     |     |            |           |           |                  |                  |

Figure 34.6-51 Information as SS Device in Case the Recipient is Device

- D0: This bit shows whether the device is self-powered or not.
- D1: This bit shows whether the device supports Remote Wakeup or not.  
SuperSpeed device is defined to set this bit to 0 and use Function Remote Wakeup instead.
- D2: This bit shows whether the device is currently enabled to initiate U1 entry or not. If this bit is 0, the device is disabled to initiate U1 entry. Regardless of whether this bit is set or not, the device can accept the request for U1 entry from the downstream port and enter U1 state.  
This bit is set to 1 on the reception of Set Feature(U1\_ENABLE) and set to 0 on the reception of Clear Feature(U1\_ENABLE). This bit is reset to 0 when the device is reset.
- D3: This bit shows whether the device is currently enabled to initiate U2 entry or not. If this bit is 0, the device is disabled to initiate U2 entry. Regardless of whether this bit is set or not, the device can accept the request for U2 entry from the downstream port and enter U2 state.  
This bit is set to 1 on the reception of Set Feature(U2\_ENABLE) and set to 0 on the reception of Clear Feature(U2\_ENABLE). This bit is reset to 0 when the device is reset.
- D4: This bit shows whether the device is currently enabled to send LTM (Latency Tolerance Message) or not. If this bit is 0, the device is disabled to send LTM.  
This bit is set to 1 on the reception of Set Feature(LTM\_ENABLE) and set to 0 on the reception of Clear Feature(LTM\_ENABLE). This bit is reset to 0 when the device is reset.

In case the recipient is device, the information returned for this request as HighSpeed or FullSpeed device is shown in **Figure 34.6-52**.

|                          |     |     |     |     |     |               |              |
|--------------------------|-----|-----|-----|-----|-----|---------------|--------------|
| D7                       | D6  | D5  | D4  | D3  | D2  | D1            | D0           |
| Reserved (Reset to Zero) |     |     |     |     |     | Remote Wakeup | Self-Powered |
| D15                      | D14 | D13 | D12 | D11 | D10 | D9            | D8           |
| Reserved (Reset to Zero) |     |     |     |     |     |               |              |

Figure 34.6-52 Information as HS/FS Device in Case the Recipient is Device

D0: This bit shows whether the device is self-powered or not.

D1: This bit shows whether the device supports Remote Wakeup or not.

The default value is 0. The value is modified on the reception of Set Feature(DEVICE\_REMOTE\_WAKEUP) or Clear Feature(DEVICE\_REMOTE\_WAKEUP). When Set Feature(DEVICE\_REMOTE\_WAKEUP) is received, the status of this bit is changed to 1. When Clear Feature(DEVICE\_REMOTE\_WAKEUP) is received, the status of this bit is changed to 0.

When this feature is enabled, device can request the remote wakeup in suspended state.

This bit is reset to 0 when the device is reset.

In case the recipient is interface, the information returned for this request as SuperSpeed device is shown in **Figure 34.6-53**.

|                          |     |     |     |     |     |                        |                                |
|--------------------------|-----|-----|-----|-----|-----|------------------------|--------------------------------|
| D7                       | D6  | D5  | D4  | D3  | D2  | D1                     | D0                             |
| Reserved (Reset to Zero) |     |     |     |     |     | Function Remote Wakeup | Function Remote Wakeup Capable |
| D15                      | D14 | D13 | D12 | D11 | D10 | D9                     | D8                             |
| Reserved (Reset to Zero) |     |     |     |     |     |                        |                                |

Figure 34.6-53 Information as SS Device in Case the Recipient is Interface

D0: This bit shows whether the interface supports Function Remote Wakeup Capable or not.

Note that Function Remote Wakeup function is used instead of Remote Wakeup function in SuperSpeed device. If the device does not support Function Remote Wakeup, it cannot request the remote wakeup in suspended state (U3).

D1: This bit shows whether the function is currently enabled to request the remote wakeup or not.

The definition of function depends on the specification of device.

The default value is 0. The value is modified on the reception of Set Feature(FUNCTION\_SUSPEND). When Set Feature(FUNCTION\_SUSPEND) is received and bit 1 in the upper byte of wIndex is 1, Function Remote Wake is enabled and the status of this bit is changed to 1. When Set Feature(FUNCTION\_SUSPEND) is received and bit1

in the upper byte of wIndex is 0, Function Remote Wake is disabled and the status of this bit is changed to 0. When this feature is enabled, device can request the remote wakeup for the suspended function. This bit is reset to 0 when the device is reset.

In case the recipient is interface, the information returned for this request as HighSpeed or FullSpeed device is shown in **Figure 34.6-54**. All fields are reserved.

Figure 34.6-54 Information as HS/FS Device in Case the Recipient is Interface

In case the recipient is endpoint, the information returned for this request as SuperSpeed, HighSpeed or FullSpeed device is shown in **Figure 34.6-55**.

Figure 34.6-55 Information as SS/HS/FS Device in Case the Recipient is Endpoint

**D0:** This bit shows the current status of Halt feature of the endpoint. If the endpoint is currently halted, the Halt feature is set to 1.

The Halt feature is required to be implemented for all interrupt and bulk endpoints.

The Halt feature might be set due to the internal status of device (when unsupported request comes, for example), or it might be set by Set Feature(ENDPOINT\_HALT).

During the feature is set to 1, the endpoint should return STALL response to any request. To return STALL response, set Pn\_CON.Pn\_RES[1:0] = 10b.

- Pn\_CON.Pn\_RES[1:0] = 10b (STALL response)

The Halt feature is cleared on the reception of ClearFeature(ENDPOINT\_HALT), SetConfiguration and SetInterface. Note that the sequence number in SS and data toggle in HS/FS is initialized on those requests. The feature might be cleared due to the internal status of device (when the cause of error is removed, for example).

When the Halt feature is reset, the endpoint changed its status not to return STALL response. Set Pn\_CON.Pn\_RES[1:0] = 01b to request the endpoint to respond in the normal mode.

- Pn\_CON.Pn\_RES[1:0] = 01b (Normal response)

SS device does not support function STALL on control endpoint.

## (6) Set Address

This request sets the device address for all future device accesses. The address is shown in wValue field of setup data.

In case this request is received, read the address in wValue field of setup data. But the device cannot update its address to the value given on Set Address until it completes the control transfer of Set Address, since it is defined in USB specification that stages after the initial setup packet assume the same device address as the setup packet.

Write the address given on Set Address to the field below before completing the status stage of the control transfer of Set Address. (That is, write the address to the field below, then P0\_CON.P0\_ST\_RES[1:0] to normal response.)

The hardware of USB3PERI updates the field to new address after it completes the status stage of the control transfer of Set Address.

- USB\_COM\_CON.DEV\_ADDR[6:0] = the value in wValue field of setup packet.

Set Address 0 has the special meaning to initialize the settings in the device. See Table 9-10 in USB3.1 specification.

## (7) Set Configuration

This request sets the device configuration. The configuration value selected is shown in lower byte of wValue field of setup data.

The configuration value shall be zero or the value shown in the configuration descriptor.

- (1) In case the configuration value matches the value shown in the configuration descriptor, do the operations as follows before the status stage of the control transfer is completed.

- Configure USB3PERI to follow the configuration selected.
- USB\_COM\_CON.CONF = 1 (USB3PERI is in configured state)

Remember the configuration value since Get Configuration might be requested later.

Then, complete the status stage of the control transfer by setting P0\_CON.P0\_ST\_RES[1:0] = 01b (normal response).

- (2) In case the configuration value is zero, it means that the device is requested to go back to address state. Do the operation as follows before the status stage of the control transfer is completed.

- USB\_COM\_CON.CONF = 0 (USB3PERI is not in configured state)

The buffer of each PIPE should be initialized as well. Do the operation noted in (f) of **Section 34.6.5.9(1), Clear Feature** for PIPEs those have been used in configured state.

Note that the clocks to Data-IN RAMs or Data-OUT RAM is suspended with the setting above. (They are suspended in unconfigured state.) In that case, the clocks to Register RAM and EP0 RAM are still running. Remember the configuration value since Get Configuration might be requested later.

Then, complete the status stage of the control transfer by setting P0\_CON.P0\_ST\_RES[1:0] = 01b (normal response).

## (8) Set Descriptor

This request is optional and may be used to update existing descriptors or new descriptors may be added.

If this request is not defined in the specification of device or the class specification which the device supports, this request is not required to be implemented.

When SetDescriptor comes, update the specified descriptor.

## (9) Set Feature

This request is used to set or enable a specific feature.

In case the recipient is device and the device works in SS, U1\_ENABLE, U2\_ENABLE, LTM\_ENABLE and B3\_NTF\_HOST\_REL are defined as feature selectors. But as B3\_NTF\_HOST\_REL is defined for OTG, it is not used for device.

- (a) When Set Feature(U1\_ENABLE) comes, enable the initiation of U1 entry of USB3PERI as follows. Note that U1\_ENABLE enables or disables only the initiation of U1 entry but the device is still allowed to accept LGO\_U1 from the downstream port and enters U1 state regardless of the feature.
  - SSIFCMD.SSIF\_UDIR[0] = 0 (The initiation of LGO\_U1 due to direct request is enabled.)
  - SSIFCMD.SSIF\_UREQ[0] = 0 (The initiation of LGO\_U1 due to timeout is enabled.)
  - PORTPMSC.U1\_TIMEOUT = U1 timeout value defined by user
- (b) When Set Feature(U2\_ENABLE) comes, enable the initiation of U2 entry of USB3PERI as follows. Note that U2\_ENABLE enables or disables only the initiation of U2 entry but the device is still allowed to accept LGO\_U2 from the downstream port and enters U2 state regardless of the feature.
  - SSIFCMD.SSIF\_UDIR[1] = 0 (The initiation of LGO\_U2 due to direct request is enabled.)
  - SSIFCMD.SSIF\_UREQ[1] = 0 (The initiation of LGO\_U2 due to timeout is enabled.)
  - PORTPMSC.U2\_TIMEOUT = U2 timeout value in received U2 Inactivity Timeout LMP
- (c) When Set Feature(LTM\_ENABLE) comes, enable the transmission of LTM (Latency Tolerance Message). Note that SS device must support U1 and U2 features, but LTM feature is optional. SS device shows whether it supports LTM feature or not on LTM capable bit in SuperSpeed USB Device Capabilities Descriptor.

In case the recipient is device and the device works in HS or FS, DEVICE\_REMOTE\_WAKEUP and TEST\_MODE are defined as feature selectors.

- (d) When Clear Feature(DEVICE\_REMOTE\_WAKEUP) comes, enable the remote wakeup function of the device. When requesting the remote wakeup, see the flow in **Section 34.6.5.8(9), Resume in USB2.0 (Initiated by Device)**.
- (e) When TEST\_MODE feature is enabled, the device is in test mode. The upper byte of wIndex of setup data specifies test mode selector and it is defined in Table 9-7 of USB2.0 specification. USB3PERI has the function for TEST\_MODE with the setting of USB20\_CON.B2\_TSTMOD [2:0] and USB20\_CON.B2\_TSTMOD\_EN. When Set Feature (TEST\_MODE) comes, set USB20\_CON.B2\_TSTMOD[2:0] and USB20\_CON.B2\_TSTMOD\_EN according to the test mode selector specified.

In case the recipient is interface and the device works in SS, FUNCTION\_SUSPEND is defined as feature selector.

- (f) The function within the device shows whether it supports Function Remote Wakeup function or not in Function Remote Wakeup Capable bit in **Figure 34.6-53**. When the function supports Function Remote Wake and Set Feature(FUNCTION\_SUSPEND) is received and the bit 1 in the upper byte of wIndex is 1, enable Function Remote Wake. When the function supports Function Remote Wake and Set Feature(FUNCTION\_SUSPEND) is received and the bit 1 in the upper byte of wIndex is 0, disable Function Remote Wake.

To request the function remote wakeup, See **Section 34.6.5.8(5), Function Remote Wakeup**.

In case the recipient is endpoint, ENDPOINT\_HALT is defined as feature selector. All of SS, HS and FS devices support the feature.

- (g) When Set Feature(ENDPOINT\_HALT) comes, set Pn\_CON.Pn\_RES[1:0] = 10b to return STALL response from the endpoint.

- Pn\_CON.Pn\_RES[1:0] = 10b (STALL response)

Note that the state machine of Stream bulk transits to Disabled state by receiving Set Feature(ENDPOINT\_HALT). If the endpoint works as the Stream bulk one, disable all transfers on the reception of Set Feature(ENDPOINT\_HALT).

It is not recommended that the endpoint 0 supports function STALL for HS and FS device. It is also defined that SS device does not support the feature. If the device does not support Halt feature for the endpoint 0, it executes the control transfer of Set Feature(ENDPOINT\_HALT) for the endpoint 0 normally but can ignore the request.

It is noted in **Section 34.6.5.9(5), Get Status** how each feature is controlled as the status of the device.

## (10) Set Interface

This request allows host to select an alternate setting of the specified interface.

In case this request is received, configure USB3PERI to follow the configuration of interface selected.

- Configure USB3PERI to follow the configuration of interface selected

As Set Interface means the initialization of selected interface as well, it is recommended to initialize the PIPEs related to the interface using Pn\_CON.Pn\_CLR. The operations as follows are required for all PIPEs related to the interface.

- Pn\_CON.Pn\_CLR = 1 (Initialization of PIPE)
- Wait for Pn\_CON.Pn\_CLR returns to 0
- Pn\_CON.Pn\_EN = 1 (Enabling the PIPE again)
- In case of DMA Transfer, Pn\_CON.Pn\_DATAIF\_EN = 1 (Enabling data interface for the PIPE again.)

Remember the alternate setting of the interface since Get Interface might be requested later.

## (11) Set Isochronous Delay

This request informs the device of the delay from the time host transmits a packet to the time it is received by the device.

As USB3PERI does not support Isochronous transfer, so there is no function to use the value received on this request.

From the viewpoint of implementation the device can return STALL response in order to show it does not support this request, or can ignore the request although it responds correctly to the control transfer of this request.

**(12) Set SEL**

This request is valid when the device works in SS and sets both the U1 and U2 System Exit Latency and the U1 or U2 exit latency for all the links between a device and a root port on the host.

When Set SEL comes, update BELT (Best Effort Latency Tolerance) value referring the information provided on this request, if required.

**(13) Synch Frame**

This request is used to set and then report an endpoint's synchronization frame.

As USB3PERI does not support Isochronous transfer, so there is no function to use the value received on this request.

From the viewpoint of implementation the device can return STALL response in order to show it does not support this request, or can ignore the request although it responds correctly to the control transfer of this request.

### 34.6.5.10 BOT Control

Bulk Only Transport (BOT) is defined as one of transfer methods in mass storage class. An example of BOT operation is described here.

#### (1) Overall

BOT consists of two bulk endpoints as its name suggests.

- Bulk OUT PIPE (for the reception of CBW or OUT data)
- Bulk IN PIPE (for the transmission of CSW or IN data)

In BOT protocol, Command Block Wrapper (CBW) is sent to request an operation in advance of IN or OUT data transfers, and Command Status Wrapper (CSW) is sent to notify the result of the operation after the IN or OUT data transfers. There are some commands which do not require the data transfers. For such command, only CBW and CSW are exchanged.

#### (2) BOT Assistance Mode

USB3PERI has BOT assistance mode. The mode is available when Pn\_MOD.Pn\_BOT is set to 1 for OUT PIPE in BOT.

In BOT assistance mode, USB3PERI notifies the reception of CBW by asserting Pn\_INT\_STA.Pn\_CBW\_STA. If an interrupt due to the bit is enabled, the interrupt is generated.

USB3PERI interprets the received packet as CBW when both of two conditions below are satisfied for the packet.

- The length of the packet is 31 bytes.
- The first 4 bytes of the packet (dCBWSignature) equals to 43425355h.

In this mode, Pn\_CON.Pn\_DATAIF\_EN of the OUT PIPE that receives CBW is disabled (reset to 0) every time CBW (the packet which satisfies two conditions above) is received. As the result, CBW is not transferred through Data Interface or on AXI DMA transfer. Pn\_CON.Pn\_DATAIF\_EN of IN PIPE is not changed.

CBW can be transferred through Data Interface or on AXI DMA transfer if Pn\_CON.Pn\_DATAIF\_EN is set to 1 again, but it is recommended to read CBW through Pn\_READ register because the software should read and decode it for BOT operation.

As CBW is a short packet in bulk transfer, the OUT PIPE in BOT enters flow control after the reception of CBW if it works as USB3.1 device. When CBW has been read through Pn\_READ register (or when it has been transferred through Data Interface or on AXI DMA transfer), USB3PERI returns ERDY from the OUT PIPE automatically. But if OUT data transfer is requested, make sure to set Pn\_CON.Pn\_DATAIF\_EN to 1 after CBW has been read or transferred.

If BOT assistance mode is not used (Pn\_MOD.Pn\_BOT = 0) for BOT transfer, the OUT PIPE in BOT does not distinguish CBW and CBW is transferred as one of short packets through Data Interface or on AXI DMA transfer. In that case Pn\_CON.Pn\_DATAIF\_EN is not disabled and Pn\_INT\_STA.Pn\_CBW\_STA is not asserted on the reception of CBW.

(USB3PERI does not know that the packet is CBW.)

The software is required to find CBW in system memory (where the received packet is transferred to) when a short packet is received.

### (3) BOT Process

It is assumed that BOT assistance mode in **Section 34.6.5.10(2), BOT Assistance Mode** and the flow of BOT process with the mode is described here.

Make sure to set Pn\_MOD.Pn\_BOT = 1.

As noted above, one bulk OUT PIPE and one bulk IN PIPE are required for BOT. For the settings of bulk OUT PIPE, see **Section 34.6.5.5(2), Bulk-OUT Process**. For the settings of bulk IN PIPE, see **Section 34.6.5.5(1), Bulk-IN Process**.

As the preparation of BOT, enable an interrupt due to Pn\_INT\_STA.Pn\_CBW\_STA of the OUT PIPE. That is, set Pn\_INT\_ENA.Pn\_CBW\_ENA of bulk OUT PIPE to 1.

- Pn\_INT\_ENA.Pn\_CBW\_ENA = 1 (Interrupt due to Pn\_INT\_STA.Pn\_CBW\_STA is enabled)

Figure 34.6-56 BOT Process Flow

#### (1) Is CBW received?

When CBW is received, Pn\_INT\_STA.Pn\_CBW\_STA is asserted and an interrupt due to it is generated.

- Interrupt due to Pn\_INT\_STA.Pn\_CBW\_STA is asserted
- Check that Pn\_INT\_STA.Pn\_CBW\_STA = 1

After the confirmation above, clear Pn\_INT\_STA.Pn\_CBW\_STA.

- Pn\_INT\_STA.Pn\_CBW\_STA = 1 (Clearing the event of the reception of CBW)

#### (2) Read CBW

Read CBW through Pn\_READ register.

## (3) Decode CBW

Decode the content of CBW which is read at (2).

If any operation other than data transfer is requested, do it here.

## (4) Which direction of transfer is requested?

If OUT transfer is requested, proceed to (5).

If IN transfer is requested, proceed to (6).

If No data transfer is requested, proceed to (7).

## (5) Read OUT data

It is assumed here that OUT data received is transferred through Data Interface or on AXI DMA transfer. Set `Pn_CON.Pn_DATAIF_EN = 1` since it is reset to 0 at the reception of CBW.

For bulk OUT transfer, see **Section 34.6.5.5(2), Bulk-OUT Process**. If two or more packets are received, repeat the flow shown there.

Proceed to (7).

## (6) Write IN data

It is assumed here that IN data to be transmitted is transferred through Data Interface or on AXI DMA transfer.

`Pn_CON.Pn_DATAIF_EN` of IN PIPE is not changed on the reception of CBW.

For bulk IN transfer, see **Section 34.6.5.5(1), Bulk-IN Process**. If two or more packets are to be transmitted, repeat the flow shown there.

Proceed to (7).

## (7) Send CSW

It is assumed here that the software prepares CSW and writes it through `Pn_WRITE` register.

Before writing CSW to the buffer of the IN PIPE, confirm that the buffer has available space.

- Check that `Pn_STA.Pn_BUFSTS = 1` for bulk IN PIPE in order to confirm that the buffer for the PIPE is available.

If the buffer has available space for CSW, write CSW through `Pn_WRITE` register. Since the size of CSW is 13 bytes, the access to `Pn_WRITE` register is required 4 times. The last write word has only 1 valid byte.

- Write CSW to `Pn_WRITE` register. 4 write accesses are required for 13 bytes of CSW.

After CSW has been written to `Pn_WRITE` register, send CSW as follows. As only 32-bit access is allowed to the register, both fields should be set in one word access.

- `Pn_CON.Pn_SEND = 1`
- `Pn_CON.Pn_BYTE_EN[1:0] = 01b` (The last word has only 1 valid byte.)

### 34.6.5.11 The Others

#### (1) USB3.1 TP Send Flow

This operational flow is the way to send any USB3.1 TP data. It is used for the TP transmission such as Device Notification TP.

Figure 34.6-57 TP Send Flow

##### (1) TP Data set

Write TP Data that will be sent to Host on the EPC registers as below.

- USB3\_TPDAT\_0 = DWORD0 of TP
- USB3\_TPDAT\_1 = DWORD1 of TP
- USB3\_TPDAT\_2 = DWORD2 of TP

##### (2) Send request

Set the following register to make a request for transmission of TP data that was set in (1).

- USB\_INT\_ENA\_1.B3\_TPSUCS\_ENA = 1 ( Interrupt due to the success of TP transmission is enabled )
- USB30\_CON.B3\_TP\_SEND = 1 ( request for transmission TP )

##### (3) TP Send completed?

Check the status of completion on the bits below.

- Interrupt due to USB\_INT\_STA\_1.B3\_TPSUCS\_STA is asserted
- Check whether USB\_INT\_STA\_1.B3\_TPSUCS\_STA = 1 ( transmission of TP is completed )
- Write 1 to the asserted bit to clear.

#### NOTE

If WarmReset or HotReset has been issued by Host when there is a request with B3\_TP\_SEND, TP may not be transmitted and interrupt due to B3\_TPSUCS\_STA may not assert.

### 34.6.6 Configuration of USB3PERI

It is described how to configure USB3PERI in this section.

#### 34.6.6.1 Prohibitions of Register Access

##### (1) Prohibited Access During a Register is Used

P0\_READ, P0\_WRITE, Pn\_READ and Pn\_WRITE registers are used to read or write a packet to each PIPE through these register.

But as noted in the subsection of each register, it is prohibited to access to other Px\_yyy registers before whole of a packet has been read or written through the register which is currently used. Px\_yyy registers. The packet might not be read or written correctly otherwise.

It is also prohibited to change the targeted PIPE of Pn\_yyy registers on PIPE\_COM.PIPE\_NUM[4:0] before read or write of a packet has been completed to the PIPE currently selected.

When P0\_WRITE or Pn\_WRITE register is used, it is required to send the packet which has been written by setting P0\_CON.P0\_SEND or Pn\_CON.Pn\_SEND before the access to other Px\_yyy registers.

Make sure to complete read or write of a packet before the access to other Px\_yyy registers, once it is started.

If Px\_yyy register is read or written in an interrupt routine, it might violate the notation without awareness. To avoid the case, mask the interrupt related to the routine during read or write of a packet, or never access to Px\_yyy registers in an interrupt service.

The lists of registers prohibited to access during P0\_READ or Pn\_READ register is used are as follows.

|                                                      |                                                        |
|------------------------------------------------------|--------------------------------------------------------|
| Prohibited to access during P0_READ register is used | P0_WRITE, Pn_READ, Pn_WRITE, Pn_STA, Pn_LNG, Pn_RSVPKT |
| Prohibited to access during Pn_READ register is used | P0_READ, P0_WRITE, P0_STA, P0_LNG, Pn_WRITE            |

The lists of registers prohibited to access during P0\_WRITE or Pn\_WRITE register is used are as follows.

|                                                        |                                                       |
|--------------------------------------------------------|-------------------------------------------------------|
| Prohibited Registers for accessing in case of P0_WRITE | P0_READ, Pn_READ, Pn_WRITE, Pn_STA, Pn_LNG, Pn_RSVPKT |
| Prohibited Registers for accessing in case of Pn_WRITE | P0_READ, P0_WRITE, P0_STA, P0_LNG, Pn_READ            |

##### (2) Prohibited Access Depends on PIPE Direction

Some registers have a specified direction of transfer for use.

P0\_READ, Pn\_READ, P0\_LNG and Pn\_LNG are only used for OUT Transfer. So these registers are prohibited to access if direction of transfer is IN (Px\_DIR = 1).

P0\_WRITE and Pn\_WRITE are only used for IN Transfer. So these registers prohibited to access if direction of transfer is OUT. (Px\_DIR = 0)

The lists of registers prohibited to access in case of Px\_MOD.Px\_DIR = 1 (for IN Transfer) are as follows.

|                                                                 |                 |
|-----------------------------------------------------------------|-----------------|
| Prohibited Registers for accessing in case of P0_MOD.P0_DIR = 1 | P0_READ, P0_LNG |
| Prohibited Registers for accessing in case of Pn_MOD.Pn_DIR = 1 | Pn_READ, Pn_LNG |

The lists of registers prohibited to access in case of Px\_MOD.Px\_DIR = 0 (for OUT Transfer) are as follows.

|                                                                 |          |
|-----------------------------------------------------------------|----------|
| Prohibited Registers for accessing in case of P0_MOD.P0_DIR = 0 | P0_WRITE |
| Prohibited Registers for accessing in case of Pn_MOD.Pn_DIR = 0 | Pn_WRITE |

## 34.7 USB Test Module (USB3TEST)

### 34.7.1 Features

This section mainly describes the USB test module (USB3TEST) which is connected between the USB3HOST and USB3PERI and the PHY module. The main functions of USB3TEST are as follows.

- Reset control
- Control of PHY input pins
- Monitoring of PHY output pins

## Section 35 PCI Express 2.0 Interface (PCIe)

This section describes the functions of the PCI Express 2.0 interface (PCIe).

This manual is a simplified version. For more information, contact a Renesas Electronics sales representative.

### 35.1 Overview

This unit has a dual structure so that the device incorporating it can operate as a root complex or endpoint device, and includes a Type 0/1 Configuration Register for this purpose. Furthermore, it has an internal DMA controller. However, limitations imposed by the AXI place restrictions on some specifications of PCI Express functionality.

#### ■ Unit Function Specifications

##### AXI Interface Specification

Little endian is only supported.

- Master interface
  - 1 port
  - Bus width: 64 bits
  - ID width: 4 bits (fixed value)
  - Interleave not supported
  - Burst type: Incremental (1 to 16 words, bursts of 4 or 8)
  - Byte-lane transfer and narrow transfer (8, 16, 32-bit lengths, only in 1 dword) are supported. Non-aligned (“unaligned”) transfer is not supported.
  - Allowable number of read/write requests: Variable (1 to 16)
  - Write interleave depth: 1
  - Protection (data/user/non-secure) can be set by using registers.
  - Access type: Normal only (exclusive or locked access not supported)
- Slave interface
  - 1 port
  - Bus width: 64 bits
  - ID width: Up to 8 bits
  - Burst type: Incremental (TYPE = INCR, LENGTH = 1 to 16, SIZE = 1/2/4/8 bytes)
  - Support for byte-lane transfer (only when valid bytes are consecutive), unaligned transfer, and narrow transfer (1, 2, and 4 bytes)
  - Number of read transactions which can be accepted: 1 to 8  
Number of write transactions which can be accepted: 1
  - Read data reordering depth: 1 to 8  
Write interleave depth: 1

- Required memory area: 16 KB or larger (variable)
  - Protection is not distinguished (reception is possible even in the case of protection).
  - Access type: Normal only (exclusive or locked access not supported)
  - Cache signals (ARCACHE/AWCACHE) are only supported for bufferable bits for writing.
- DMAC
    - DMA method: Register control, descriptor control
    - Number of channels: 8
    - Allowable number of requests to be issued (the maximum total number: 8. When DMAC ch. 1 issues eight PCIe-MRd/MW requests, other channels cannot issue requests).

PCIe MRd: Up to 8/ch    PCIe MWr: 1/ch  
 AXI Read: 1/ch    AXI Write: 1/ch

#### PCI Express Specification (Compliant with the PCI Express Base Specification 4.0)

- PCI Express Gen1 (2.5 (GT/s))/Gen2 (5.0 (GT/s))
- Root Complex (RC) / Endpoint (EP) Applications, Type 0/1 Configuration Register
- Supports one lane (×1) or two lanes (×2)
- Data payload: up to 128 bytes; read request size: up to 512 bytes
- Virtual channels are not supported (only VC0 supported)
- Number of outstanding transfers: 1 to 8
- Dynamic control of speed up/down configuration
- Clock Power Management is not supported (P1.CPM, P2.CPM not supported)
- Power Management (ASPM supported)
- Error handling/logging (AER supported)
- Replay FIFO with ECC
- Internal Memory without parity
- Number of Support Functions: 2
- Number of DMAC channels: 8

The initial values of configuration registers for vendor ID, device ID, revision ID, class code, subsystem vendor ID, subsystem ID, and base address register mask are 0. Set appropriate values in the registers before the start of link up.  
 L1PM substates are not supported.

## 35.2 TOP Pins

### 35.2.1 Pin Functions

This section gives the list of top-level pins of this unit.

#### 35.2.1.1 List of External Pins

**Table 35.2-1** lists the external pins of the PCI.

Table 35.2-1 List of External Pins

| Pin name  | I/O    | Function                                                       |
|-----------|--------|----------------------------------------------------------------|
| PCRXD0P   | Input  | Serial data input for Lane0 (positive)                         |
| PCRXD0M   | Input  | Serial data input for Lane0 (negative)                         |
| PCRXD1P   | Input  | Serial data input for Lane1 (positive)                         |
| PCRXD1M   | Input  | Serial data input for Lane1 (negative)                         |
| PCTXD0P   | Output | Serial data output for Lane0 (positive)                        |
| PCTXD0M   | Output | Serial data output for Lane0 (negative)                        |
| PCTXD1P   | Output | Serial data output for Lane1 (positive)                        |
| PCTXD1M   | Output | Serial data output for Lane1 (negative)                        |
| PCREFCKP  | Input  | Reference clock input (positive) 100 MHz                       |
| PCREFCKM  | Input  | Reference clock input (negative) 100 MHz                       |
| PCREXT    | Input  | External reference resistor connection: 8.2k $\Omega$ $\pm$ 1% |
| PCRSTOUTB | Output | Reset output                                                   |

### 35.2.1.2 List of Internal Pins

**Table 35.2-2** lists the internal pins of this unit.

Table 35.2-2 List of Internal Pins (1/2)

| Pin name                               | I/O    | Function                                                                                                   |
|----------------------------------------|--------|------------------------------------------------------------------------------------------------------------|
| FLR_REQ[1:0]                           | Output | FLR request output                                                                                         |
| FLR_RESET[1:0]                         | Input  | FLR input                                                                                                  |
| INTX_EP_F0                             | Input  | INTX interrupt signal input for Function #0 for Endpoint<br>(Level signal input: 2 or more cycles of ACLK) |
| INTX_EP_F1                             | Input  | INTX interrupt signal input for Function #1 for Endpoint<br>(Level signal input: 2 or more cycles of ACLK) |
| UI_EXTMSI_VAL0                         | Input  | MSI interrupt notification pin for Endpoint                                                                |
| UI_EXTMSI_VAL1                         | Input  | MSI interrupt notification pin for Endpoint                                                                |
| UI_EXTMSI_VAL2                         | Input  | MSI interrupt notification pin for Endpoint                                                                |

35.3 Block Diagram

The figure below is a block diagram of the PCI.

Figure 35.3-1 Block Diagram

35.3.1 Reset

A software reset by the register can be used for this unit. **Table 35.3-1** lists the software resets.

Table 35.3-1 List of Software Resets

| Reset Name    | Reset Control Register              |
|---------------|-------------------------------------|
| RST_B         | Reset Registers (offset:310h) bit 0 |
| RST_GP_B      | Reset Registers (offset:310h) bit 1 |
| RST_RSM_B     | Reset Registers (offset:310h) bit 2 |
| RST_CFG_B     | Reset Registers (offset:310h) bit 3 |
| RST_LOAD_B    | Reset Registers (offset:310h) bit 4 |
| RST_PS_B      | Reset Registers (offset:310h) bit 5 |
| ARESETn (CPG) | Reset Control Register 3 bit 12     |

**Note:** In addition, there is a function level reset (FLR) which is only available in EP operation.

### 35.4 Register Descriptions (Root Complex Mode)

The following lists the registers incorporated in this unit.  
For the register base address (<PCI\_S0\_REG\_base>), see the section of Address Map.

CAUTION

The results of access to reserved bit areas, debug bit areas, and undefined areas are not guaranteed. The combination of reserved, debug, and undefined areas includes cases where the initial values will be non-zero, and the results of changes to such values are not guaranteed.

Registers with the HwInit attribute

Some registers with the RO attribute stated in the PCI Express Base Specification are writable at the time of initialization. When writing to these registers, CFG\_HWINIT\_EN (Permission Register (offset: 300h) bit[2]) must be set to 1b.

The following is the outline of categories of the register space within this unit.

|                                             |                                 |
|---------------------------------------------|---------------------------------|
| AXI Bridge Registers                        | <PCI_S0_REG_base> + 0000h-1FFCh |
| Reserved                                    | <PCI_S0_REG_base> + 2000h-5FFCh |
| PCI Express Configuration Registers (Type1) | <PCI_S0_REG_base> + 6000h-6FFCh |
| Reserved                                    | <PCI_S0_REG_base> + 7000h-7FFCh |

Access to the reserved spaces above is prohibited.

### 35.4.1 List of AXI Bridge Registers

The table below lists the AXI bridge registers. Unless specifically stated otherwise, byte, word, and double word access are all possible.

Table 35.4-1 AXI Bridge Registers (1/5)

| Offset Address                    | Register Name                              | Abbreviation      | Initial Value | Access Unit (bits) |
|-----------------------------------|--------------------------------------------|-------------------|---------------|--------------------|
| Reserved 00h to 7Ch               |                                            |                   |               |                    |
| 00 to 7Ch                         | Reserved                                   | —                 | —             | —                  |
| Request Issuing 80h to FCh        |                                            |                   |               |                    |
| 80h                               | Request Data Register 0                    | PCI_RC_REQDATA0   | xxxx_xxxxh    | 32                 |
| 84h                               | Request Data Register 1                    | PCI_RC_REQDATA1   | xxxx_xxxxh    | 32                 |
| 88h                               | Request Data Register 2                    | PCI_RC_REQDATA2   | xxxx_xxxxh    | 32                 |
| 8Ch                               | Request Receive Data Register              | PCI_RC_REQRCVDAT  | xxxx_xxxxh    | 32                 |
| 90h                               | Request Address Register 1                 | PCI_RC_REQADR1    | xxxx_xxxxh    | 32                 |
| 94h                               | Request Address Register 2                 | PCI_RC_REQADR2    | xxxx_xxxxh    | 32                 |
| 98h                               | Request Byte Enable Register               | PCI_RC_REQBE      | 0000_000Fh    | 32                 |
| 9Ch                               | Request Issue Register                     | PCI_RC_REQISS     | 0000_0000h    | 32                 |
| A0h to FCh                        | Reserved                                   | —                 | —             | —                  |
| PCI Interruption 100h to 11Ch     |                                            |                   |               |                    |
| 100h                              | MSI Receive Window Address Register        | PCI_RC_MSIRCVWADR | 0000_0000h    | 32                 |
| 104h                              | Reserved                                   | —                 | —             | —                  |
| 108h                              | MSI Receive Window Mask Register           | PCI_RC_MSIRCVWSK  | 0000_0003h    | 32                 |
| 10Ch                              | Reserved                                   | —                 | —             | —                  |

| 1168h                                    | PCIe Destination 6 (Lower) Register | PCI_RC_PDESTLO6 | 0000_0000h    | 32                 |
| 116Ch                                    | PCIe Destination 6 (Upper) Register | PCI_RC_PDESTUP6 | 0000_0000h    | 32                 |

Table 35.4-1 AXI Bridge Registers (5/5)

| Offset Address | Register Name                       | Abbreviation    | Initial Value | Access Unit (bits) |
|----------------|-------------------------------------|-----------------|---------------|--------------------|
| 1170h          | PCIe Window Base 7 Register         | PCI_RC_PWBASE7  | 0000_0000h    | 32                 |
| 1174h          | PCIe Window Mask 7 Register         | PCI_RC_PWMASK7  | 0000_0FFFh    | 32                 |
| 1178h          | PCIe Destination 7 (Lower) Register | PCI_RC_PDESTLO7 | 0000_0000h    | 32                 |
| 117Ch          | PCIe Destination 7 (Upper) Register | PCI_RC_PDESTUP7 | 0000_0000h    | 32                 |
| 1180h to 1FFCh | Reserved* <sup>2</sup>              | —               | —             | —                  |

**Note:** Debug: Registers for use in debugging by Renesas. Access to these registers may lead to a malfunction.  
 Reserved: Reserved registers. The results of access to these registers and operation of the core through such access are not guaranteed.

Note 1. The addresses listed in the above table are those for channel 0. These addresses should be read as the addresses for the other DMAC channels according to the table below.

| Channel Offset Address |           |
|------------------------|-----------|
| offset + 000h          | Channel 0 |
| offset + 080h          | Channel 1 |
| offset + 100h          | Channel 2 |
| offset + 180h          | Channel 3 |
| offset + 200h          | Channel 4 |
| offset + 280h          | Channel 5 |
| offset + 300h          | Channel 6 |
| offset + 380h          | Channel 7 |

*Example)*

Channel 0: DMA Descriptor Control Register (offset: 920h = 920h + 000h)  
 Channel 1: DMA Descriptor Control Register (offset: 9A0h = 920h + 080h)  
 Channel 2: DMA Descriptor Control Register (offset: A20h = 920h + 100h)  
 Channel 3: DMA Descriptor Control Register (offset: AA0h = 920h + 180h)  
 Channel 4: DMA Descriptor Control Register (offset: B20h = 920h + 200h)  
 Channel 5: DMA Descriptor Control Register (offset: BA0h = 920h + 280h)  
 Channel 6: DMA Descriptor Control Register (offset: C20h = 920h + 300h)  
 Channel 7: DMA Descriptor Control Register (offset: CA0h = 920h + 380h)

Note 2. Though the address range from 1200h to 13FCh includes the AXI bridge registers for endpoint, access to this area is prohibited (the address configuration of the AXI bridge registers does not vary whether operation is as a root complex or endpoint).

## 35.4.2 List of PCI Express Configuration Registers

### 35.4.2.1 Type 1 (for Root Complex)

The table below lists the PCI Express configuration registers.

Table 35.4-2 PCI Express Configuration Registers (1/2)

| Offset Address                            | Register Name                            | Abbreviation    | Initial Value | Access Unit (bits) |
|-------------------------------------------|------------------------------------------|-----------------|---------------|--------------------|
| Common Configuration Space                |                                          |                 |               |                    |
| 6000h                                     | Vendor and Device ID                     | PCI_RC_VID      | 0000_0000h    | 32                 |
| 6004h                                     | Command and Status                       | PCI_RC_COM_STA  | 0010_0000h    | 32                 |
| 6008h                                     | Revision ID and Class Code               | PCI_RC_RID_CC   | 0000_0000h    | 32                 |
| 600Ch                                     | Cache Line and Header Type               | PCI_RC_CL_HT    | 0001_0000h    | 32                 |
| Configuration Space                       |                                          |                 |               |                    |
| 6010h                                     | Base Address Register 0                  | PCI_RC_BAR0     | 0000_0004h    | 32                 |
| 6014h                                     | Base Address Register 1                  | PCI_RC_BAR1     | 0000_0000h    | 32                 |
| 6018h                                     | Bus Number Register                      | PCI_RC_BNR      | 0000_0000h    | 32                 |
| 601Ch                                     | I/O Base/Limit and Secondary Status      | PCI_RC_IOBL_SS  | 0000_0000h    | 32                 |
| 6020h                                     | Memory Base/Limit Register               | PCI_RC_MEMBL    | FFF0_FFF0h    | 32                 |
| 6024h                                     | Prefetchable Memory Base/Limit Register  | PCI_RC_PMBL     | 0001_0001h    | 32                 |
| 6028h                                     | Prefetchable Base Upper 32bits Register  | PCI_RC_PBUP32   | 0000_0000h    | 32                 |
| 602Ch                                     | Prefetchable Limit Upper 32bits Register | PCI_RC_PLUP32   | 0000_0000h    | 32                 |
| 6030h                                     | I/O Base/Limit Upper 16bits Register     | PCI_RC_IOBLUP16 | 0000_0000h    | 32                 |

**Note:** "Specific Registers" refers to registers specific to this unit.

Note 1. Writing all 1b's is recommended in the initial settings for operation as a root complex.

35.4.3 Register Descriptions (Root Complex Mode)

The function description of each register is given below.

35.4.3.1 AXI Bridge Registers

(1) Request Data Register m (PCI\_RC\_REQDATAm) (m = 0 to 2)

This register issues various requests.

Table 35.4-3 PCI\_RC\_REQDATAm Register Contents

| Bit Position | Bit Name     | Description                            |
|--------------|--------------|----------------------------------------|
| 31 to 0      | Request Data | Sets write data for issuing a request. |

Table 35.4-4

|                                   | Request Data Register 0 | Request Data Register 1 | Request Data Register 2 |
|-----------------------------------|-------------------------|-------------------------|-------------------------|
| Zero-Length Read Request          | Invalid                 | Invalid                 | Invalid                 |
| Config Write                      | Invalid                 | Invalid                 | Write data              |
| Config Read                       | Invalid                 | Invalid                 | Invalid                 |
| Message Request                   | 3rd Header              | 4th Header              | Invalid                 |
| Message Request with data payload | 3rd Header              | 4th Header              | Message data            |

**Note:** The bits should be set to 0 for the requests indicated as "Invalid".

(2) Request Receive Data Register (PCI\_RC\_REQRCVDAT)

This register indicates the data read on reception of the completion response after issuing a read request.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 008Ch  
Initial Value: xxxx\_xxxxh

Table 35.4-5 PCI\_RC\_REQRCVDAT Register Contents

| Bit Position | Bit Name             | Description                                                                                                                                                            |
|--------------|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | Request Receive Data | After issuing a read request, the data read on reception of the completion response are set in these bits. However, these bits are invalid for various write requests. |

**(3) Request Address Register 1 (PCI\_RC\_REQADR1)**

This register issues requests to PCIe.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0090h

**Initial Value:** xxxx\_xxxxh

Table 35.4-6 PCI\_RC\_REQADR1 Register Contents

| Bit Position | Bit Name               | Description                                                |
|--------------|------------------------|------------------------------------------------------------|
| 31 to 0      | Request Address [31:0] | Sets the address and so forth for use in issuing requests. |

Table 35.4-7

|                                   | [31:27]    | [26:24]      | [23:19]  | [18:16]         |
|-----------------------------------|------------|--------------|----------|-----------------|
| Zero-Length Read Request          | Address    |              |          |                 |
| Config Write                      | Bus number |              | Reserved | Function number |
| Config Read                       | Bus number |              | Reserved | Function number |
| Message Request                   | Reserved   | Routing type | Reserved | Reserved        |
| Message Request with data payload | Reserved   | Routing type | Reserved | Reserved        |

|                                   | [15:12]  | [11:8]           | [7:2]           | [1:0]    |
|-----------------------------------|----------|------------------|-----------------|----------|
| Zero-Length Read Request          | Address  |                  |                 | Reserved |
| Config Write                      | Reserved | Ext. Reg. number | Register number | Reserved |
| Config Read                       | Reserved | Ext. Reg. number | Register number | Reserved |
| Message Request                   | Reserved | Reserved         | Message code    |          |
| Message Request with data payload | Reserved | Reserved         | Message code    |          |

**Note:** The bits should be set to 0 for the requests indicated as "Reserved".

(4) Request Address Register 2 (PCI\_RC\_REQADR2)

This register issues requests to PCIe.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0094h  
Initial Value: xxxx\_xxxxh

Table 35.4-8 PCI\_RC\_REQADR2 Register Contents

| Bit Position | Bit Name                | Description                                                |
|--------------|-------------------------|------------------------------------------------------------|
| 31 to 0      | Request Address [63:32] | Sets the address and so forth for use in issuing requests. |

Table 35.4-9

|                                   | [31:0]  |
|-----------------------------------|---------|
| Zero-Length Read Request          | Address |
| Config Write                      | Invalid |
| Config Read                       | Invalid |
| Message Request                   | Invalid |
| Message Request with data payload | Invalid |

**Note:** The bits should be set to 0 for the requests indicated as "Invalid".

(5) Request Byte Enable Register (PCI\_RC\_REQBE)

This register specifies the 1st DW byte enable bit of the TLP header when issuing a request to PCIe.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0098h  
Initial Value: 0000\_000Fh

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

(7) MSI Receive Window Address Register (PCI\_RC\_MSIRCVWADR)

This register sets the start address of the MSI memory space to receive.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0100h  
Initial Value: 0000\_0000h

Table 35.4-14 PCI\_RC\_MSIRCVWADR Register Contents

| Bit Position | Bit Name                          | Description                                                                                                                                                                                                                                                                                                      |
|--------------|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 3      | MSI Receive Window Address [31:3] | Sets MSI receive window address. The address should be aligned with the size set in the MSI Receive Mask bits. When a non-aligned address is set, the address bits for which the MSI Receive Window Mask bits have been set become 0.<br>* To change this register, set the MSI Receive Window Enable bit to 0b. |
| 2, 1         | —                                 | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                             |
| 0            | MSI Receive Window Enable         | Enables the MSI receive window.<br>0b: Disable the window.<br>1b: Enable the window.                                                                                                                                                                                                                             |

(8) MSI Receive Window Mask Register (PCI\_RC\_MSIRCVWSK)

This register specifies the size of the area from the address set in the MSI Receive Window Address bits.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0108h  
Initial Value: 0000\_0003h

Table 35.4-15 PCI\_RC\_MSIRCVWSK Register Contents

| Bit Position | Bit Name                      | Description                                                                                                                                                                                                                                                                          |
|--------------|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 2      | MSI Receive Window Mask[31:2] | Set the lower bits of the reserved area to 1b (min. 4-byte space; max. 4-Gbyte space).<br>Example settings are as follows.<br>0h: 4-byte space<br>1b: 8-byte space<br>7fh: 2048-byte space<br><br><i>Note:</i> To change this register, set the MSI Receive Window Enable bit to 0b. |
| 1, 0         | MSI Receive Window Mask[1:0]  | Fixed to 11b.<br>The MSI Receive Window Mask [1:0] bits are always set to Mask.                                                                                                                                                                                                      |

**(9) PCI INTx Receive Interrupt Enable Register (PCI\_RC\_PINTRCVIE)**

This register enables INTx\_RC interrupts.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0110h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20                                    | 19                                     | 18                                     | 17                                     | 16                                     |

**(10) PCI INTx Receive Interrupt Status Register (PCI\_RC\_PINTRCVIS)**

This register indicates the INTx\_RC interrupt factor. When Assert\_INTx is received in response to a message request from PCIe, the corresponding bit in this register is set and interrupt INTx\_RC is asserted. When Deassert\_INTx is received in response to a message request, the corresponding bit in this register is cleared and interrupt INTx\_RC is deasserted. Although this register can be cleared by writing 1b by software, it is not recommended to clear this bit by the software itself during normal operation for interrupts on the bus for PCIe. The fields of this register are set if each factor is detected, regardless of the setting of the PCI\_INTx\_Receive\_Interrupt\_Enable register for RC.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0114h

**Initial Value:** 0000\_0000h

**(11) Message Receive Interrupt Enable Register (PCI\_RC\_MSGRCVIE)**

This register controls enabling of MSG\_INT in response to the reception of message requests other than INTx and error-related messages.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0120h

**Initial Value:** 0000\_0000h

| 15 to 0      | —                                            | Fixed to 0b.                                                                                               |

**(12) Message Receive Interrupt Status Register (PCI\_RC\_MSGRCVIS)**

This register is a status register that indicates the reception of message requests other than INTx and error-related messages. The value of this register is reflected in MSG\_INT. Only the message code is used to judge the message type. The validity of routing and validity of Msg/MsgD selection are not verified. The corresponding message is considered to have been received.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0124h

**Initial Value:** 0000\_0000h

Table 35.4-20 PCI\_RC\_MSGCODE Register Contents

| Bit Position | Bit Name        | Description                                                                                                                              |
|--------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 16     | —               | Reserved. These bits are read as 0b.                                                                                                     |
| 15 to 8      | Message Code    | Stores the code of the last received message.                                                                                            |
| 7 to 5       | Routing         | Stores routing of the last received message.                                                                                             |
| 4 to 1       | —               | Reserved. These bits are read as 0b.                                                                                                     |
| 0            | Message Payload | Stores the presence or absence of the data payload of the last received message.<br>1b: MsgD (with payload)<br>0b: Msg (without payload) |

**Note:** When a Power Management message (PME\_TO\_Ack Message, PME\_Turn\_Off Message, PM\_PME Message, PM\_Active\_State\_Nak Message) is received, this register is not written.

(14) Message Data Register (PCI\_RC\_MSGDATA)

This register stores the data of the last received message.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0134h  
Initial Value: 0000\_0000h

Table 35.4-21 PCI\_RC\_MSGDATA Register Contents

| Bit Position | Bit Name     | Description                                                                                                                                                          |
|--------------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | Message Data | Stores the first DW data of the last received message. Updated only when MsgD (with data) is received, and retains previous data when Msg (without data) is received |

**Note:** When a Power Management message (PME\_TO\_Ack Message, PME\_Turn\_Off Message, PM\_PME Message, PM\_Active\_State\_Nak Message) is received, this register is not written.

(15) Message Header 3rdDW Register (PCI\_RC\_MSGH3DW)

This register stores the header (the 3rd DW) of the last received message.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0138h  
Initial Value: 0000\_0000h

Table 35.4-22 PCI\_RC\_MSGH3DW Register Contents

| Bit Position | Bit Name              | Description                                                  |
|--------------|-----------------------|--------------------------------------------------------------|
| 31 to 0      | Message Header 3rd DW | Stores the header (the 3rd DW) of the last received message. |

**Note:** When a Power Management message (PME\_TO\_Ack Message, PME\_Turn\_Off Message, PM\_PME Message, PM\_Active\_State\_Nak Message) is received, this register is not written.

(16) Message Header 4thDW Register (PCI\_RC\_MSGH4DW)

This register stores the header (the 4th DW) of the last received message.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 013Ch  
Initial Value: 0000\_0000h

Table 35.4-23 PCI\_RC\_MSGH4DW Register Contents

| Bit Position | Bit Name              | Description                                                  |
|--------------|-----------------------|--------------------------------------------------------------|
| 31 to 0      | Message Header 4th DW | Stores the header (the 4th DW) of the last received message. |

**Note:** When a Power Management message (PME\_TO\_Ack Message, PME\_Turn\_Off Message, PM\_PME Message, PM\_Active\_State\_Nak Message) is received, this register is not written.

**(17) Interrupt Table Register (PCI\_RC\_INTTABLE)**

This register is an index of interrupt factors. The interrupt signal (active high) status of each category can be monitored in a list.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0140h

**Initial Value:** 00xx\_0000h

|               |       |    |    |    |       |             |              |         |    |    |    |           |         |         |         |         |

Table 35.4-24 PCI\_RC\_INTTABLE Register Contents

| Bit Position | Bit Name     | Description                                  |
|--------------|--------------|----------------------------------------------|
| 31 to 15     | Debug        | Debug register                               |
| 14 to 12     | —            | Reserved. These bits are read as 0b.         |
| 11           | Debug        | Debug register                               |
| 10           | AXI_ERR_INT  | Error interrupt monitor register             |
| 9            | PCIE_EVT_INT | Event interrupt monitor register             |
| 8            | MSG_INT      | Message interrupt monitor register           |
| 7 to 5       | —            | Reserved. These bits are read as 0b.         |
| 4            | INTMSI_RC    | INT_MSI reception interrupt monitor register |
| 3            | INTD_RC      | INTD_RC reception interrupt monitor register |
| 2            | INTC_RC      | INTC_RC reception interrupt monitor register |
| 1            | INTB_RC      | INTB_RC reception interrupt monitor register |
| 0            | INTA_RC      | INTA_RC reception interrupt monitor register |

**Note:** See the description of the terminal of the same name for details of the register.

Debug: Registers for use in debugging by Renesas. Note that a change from the initial value may lead to a malfunction.

**(18) PCIe Event Interrupt Enable 0 Register (PCI\_RC\_PEIE0)**

This register enables interrupts of the various PCI Express event factors. This register enables writing to the PCIe Event Interrupt Status 0 Register (address: <PCI\_S0\_REG\_base> + 0204h). See the description of this status register for details of the factors.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0200h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30                           | 29                           | 28              | 27 | 26 | 25    | 24    | 23    | 22 | 21    | 20 | 19 | 18 | 17 | 16 |

**(19) PCIe Event Interrupt Status 0 Register (PCI\_RC\_PEIS0)**

This register is a status register that indicates each PCI Express event. Set to 1b by the factor in the table. After checking the factor, write 1b to clear it.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0204h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30                        | 29                        | 28           | 27 | 26 | 25    | 24  | 23    | 22  | 21    | 20  | 19  | 18  | 17  | 16  |

**(20) PCIe Event Interrupt Enable 1 Register (PCI\_RC\_PEIE1)**

This register enables parity error and ECC error interrupts. When each bit is set to the valid setting, the value of each corresponding status bit of the PCIe event interrupt status 1 register (address: <PCI\_S0\_REG\_base> + 020Ch) becomes valid.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0208h

**Initial Value:** 0000\_0000h

Table 35.4-28 PCI\_RC\_PEIS1 Register Contents

| Bit Position | Bit Name                             | Description                                                                                                                                                                                                                                                              |
|--------------|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 18     | —                                    | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                     |
| 17           | TXB_PARITY_ERR                       | TXB_PARITY_ERR interrupt. Notification of parity error interrupts in the Tx buffer mounted on the Transaction Layer. It is cleared by writing 1b. Writing 0b has no effect.                                                                                              |
| 16           | ERR_RPC_REPLAYFIFO_PERR              | ERR_RPC_REPLAYFIFO_PERR interrupt. Notification of parity error interrupts in the replay FIFO mounted on the data link layer. It is cleared by writing 1b. Writing 0b has no effect.                                                                                     |
| 15 to 10     | —                                    | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                     |
| 9            | ERR_REPLAY_UPPER_CORRECTABLE_ERROR   | ERR_REPLAY_UPPER_CORRECTABLE_ERROR interrupt. Notification of ECC 1-bit error (correctable error) occurrence interrupts in the upper 64 bits of the data bus of the replay FIFO mounted on the data link layer. It is cleared by writing 1b. Writing 0b has no effect.   |
| 8            | ERR_REPLAY_LOWER_CORRECTABLE_ERROR   | ERR_REPLAY_LOWER_CORRECTABLE_ERROR interrupt. Notification of ECC 1-bit error (correctable error) occurrence interrupts in the lower 64 bits of the data bus of the replay FIFO mounted on the data link layer. It is cleared by writing 1b. Writing 0b has no effect.   |
| 7 to 2       | —                                    | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                     |
| 1            | ERR_REPLAY_UPPER_UNCORRECTABLE_ERROR | ERR_REPLAY_UPPER_UNCORRECTABLE_ERROR interrupt. Notification of ECC 2-bit error (correctable error) occurrence interrupts in the upper 64 bits of the data bus of the replay FIFO mounted on the data link layer. It is cleared by writing 1b. Writing 0b has no effect. |
| 0            | ERR_REPLAY_LOWER_UNCORRECTABLE_ERROR | ERR_REPLAY_LOWER_UNCORRECTABLE_ERROR interrupt. Notification of ECC 2-bit error (correctable error) occurrence interrupts in the lower 64 bits of the data bus of the replay FIFO mounted on the data link layer. It is cleared by writing 1b. Writing 0b has no effect. |

(22) AXI Master Error Interrupt Enable Register (PCI\_RC\_AMEIE)

This register enables the AXI master error interrupt.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0210h  
Initial Value: 0000\_0000h

|               |    |    |    |    |                          |    |    |    |    |    |    |    |                         |    |    |    |

| 11 to 8      | Write SLVERR INT [3:0] | <p>Indicates that an unrecoverable error was detected on the AXI slave port (the response to the transaction is SLVERR).</p> <p>Bit 11: Burst length error<br/>SAWLEN does not match the burst length of the data received by the data channel.</p> <p>Bit 10: ID mismatch<br/>SAWID does not match SWID received by the data channel.</p> <p>Bit 9: Burst type invalid<br/>SAWBURST is 11b (undefined). When SAWBURST is 10b (wrapping) and the burst length is other than 2, 4, 8, and 16.</p> <p>Bit 8: Data size invalid<br/>SAWSIZE is 100b to 111b (greater than the AXI bus width or not supported).</p> <p>Each bit means the following.</p> <p>0b: No error detected</p> <p>1b: Error detected</p> <p>It is cleared by writing 1b. Writing 0b has no effect.</p> |
| 7 to 2       | —                      | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 1, 0         | Read SLVERR INT [1:0]  | <p>Indicates that an unrecoverable error was detected on the AXI slave port (the response to the transaction is SLVERR).</p> <p>Bit 1: Burst type invalid<br/>SAWBURST is 11b (undefined). When SAWBURST is 10b (wrapping) and the burst length is other than 2, 4, 8, and 16.</p> <p>Bit 0: Data size invalid<br/>SAWSIZE is 100b to 111b (greater than the AXI bus width or not supported).</p> <p>Each bit means the following.</p> <p>0b: No error detected</p> <p>1b: Error detected</p> <p>These bits are cleared by writing 1b. Writing 0b has no effect.</p>                                                                                                                                                                                                      |

(26) AXI Slave Error Interrupt Status 3 Register (PCI\_RC\_ASEIS3)

This register indicates the AXI ID at the time of the first AXI slave error.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0230h  
Initial Value: 0000\_0000h

Table 35.4-33 PCI\_RC\_ASEIS3 Register Contents

| Bit Position | Bit Name | Description                                                                                                                                                                                                                                                                      |
|--------------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | ERR ID   | Saves the ID at the time of the first error of the AXI Slave Error Interrupt Status 1 register (address: 8503_0224h). Only the first error is saved. A new error ID can be saved when bits [11:8] and bits [1:0] of the AXI Slave Error Interrupt Status 1 register are cleared. |

(27) Permission Register (PCI\_RC\_PERM)

This register controls access to the CFGU register.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0300h  
Initial Value: 0000\_0000h

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |                       |       |    |

| Bit Position | Bit Name      | Description                                                                |
|--------------|---------------|----------------------------------------------------------------------------|
| 31 to 3      | —             | Reserved. These bits are read as 0b.                                       |
| 2            | CFG_HWINIT_EN | Output to the CFG_HWINIT_EN pin. Used for register access control in CFGU. |
| 1, 0         | Debug         | Debug register                                                             |

**(28) Reset Register (PCI\_RC\_RESET)**

This register resets the PCIe core. Supplied to the internal core by OR with the pin of the same name. For details of each pin, see the terminal information. The write value is saved when accessed from the AXI, but a low-level pulse is generated when the PCIe writes 0b. However, when the AXI has already written 0b, the signal remains at the low level. Writing 1b from the PCIe will be ignored.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0310h

**Initial Value:** 0000\_00xxh

| 7 to 0       | ASPM L1 Idle Time | Sets the idle time for AXI transactions that will be checked by the unit during the transition to ASPM L1. 8 bits are set by these bits, and FFh is added to the lower 8 bits to form the idle time cycles. One condition for a transition to ASPM L1 is to confirm its idle time.<br>00h: 256 [ACLK]<br>01h: 512 [ACLK]<br>...<br>FFh: 65536 [ACLK] |

(32) Debug Output 1 Register (PCI\_RC\_DBGOUT1)

This register is for debugging.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0384h  
Initial Value: 0000\_0000h

Table 35.4-39 PCI\_RC\_DBGOUT1 Register Contents

| Bit Position | Bit Name | Description                                                                                                            |

**(38) PCIe Core Control 2 Register (PCI\_RC\_PCCTRL2)**

This register controls the link speed/width change in the PCI Express core.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0410h

**Initial Value:** 003E\_0000h

After confirming assertion of UI_LINK_SPEED_CHANGE_DONE of PCIe Core Status 2 Register (address: <PCI_S0_REG_base> + 0414h) bit [28], set 1b0. |

**(39) PCIe Core Status 2 Register (PCI\_RC\_PCSTAT2)**

This register indicates the status of the link speed/width change in the PCI Express core.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0414h

**Initial Value:** xxxx\_xxxxh

| 28 to 24     | DMA_CH7_vec    | Specifies the MSI interrupt vector transmitted by DMAC ch. 7.                                                                                                                                 |
| 23, 22       | —              | Reserved. These bits are read as 0b.                                                                                                                                                          |
| 21           | DMA_CH6_MSI_EN | DMA Ch6 MSI Enable<br>0b: MSI is not used (DMA interrupt notification by the DMA_INT pin).<br>1b: MSI is used.<br>For the RC function, MSI transmission is prohibited, so fix this bit to 0b. |
| 20 to 16     | DMA_CH6_vec    | Specifies the MSI interrupt vector transmitted by DMAC ch. 6.                                                                                                                                 |
| 15, 14       | —              | Reserved. These bits are read as 0b.                                                                                                                                                          |
| 13           | DMA_CH5_MSI_EN | DMA Ch5 MSI Enable<br>0b: MSI is not used (DMA interrupt notification by the DMA_INT pin).<br>1b: MSI is used.<br>For the RC function, MSI transmission is prohibited, so fix this bit to 0b. |
| 12 to 8      | DMA_CH5_vec    | Specifies the MSI interrupt vector transmitted by DMAC ch. 5.                                                                                                                                 |
| 7, 6         | —              | Reserved. These bits are read as 0b.                                                                                                                                                          |
| 5            | DMA_CH4_MSI_EN | DMA Ch4 MSI Enable<br>0b: MSI is not used (DMA interrupt notification by the DMA_INT pin).<br>1b: MSI is used.<br>For the RC function, MSI transmission is prohibited, so fix this bit to 0b. |
| 4 to 0       | DMA_CH4_vec    | Specifies the MSI interrupt vector transmitted by DMAC ch. 4.                                                                                                                                 |

**Note:** DMA\_CHx\_vec should be fixed to 0\_0000b for the RC function.

(43) DMA Control Register (PCI\_RC\_DMACTRL)

This register sets the maximum size of read requests which can be issued to the PCIe core as a DMAC function. Use the initial setting (128 bytes). This setting is common to all DMA channels.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0800h  
Initial Value: 0000\_0000h

**(46) DMA Channel Control Register m (PCI\_RC\_DMACHCTLm) (m = 0 to 7)**

This register sets the control method for each DMA channel. Set either register type or descriptor type.

- Setting QUE\_EN = 1 and QUE\_CLR = 1 is prohibited during register-type DMA transfer (TDMA\_EN = 1).
- Setting RDMA\_EN = 1 is prohibited during descriptor-type DMA transfer (QUE\_EN = 1).

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0900h (m = 0)  
 <PCI\_S0\_REG\_base> + 0980h (m = 1)  
 <PCI\_S0\_REG\_base> + 0A00h (m = 2)

Table 35.4-53 PCI\_RC\_DMACHCTLm Register Contents

| Bit Position | Bit Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 9      | —        | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 8            | QUE_CLR  | Queue Clear<br>The queue is cleared by writing 1b. The descriptor lists registered in the queue (those waiting for execution and the one currently being executed) are all cleared.<br>The value read is always 0b. Writing 1b is prohibited when QUE_EN is set.                                                                                                                                                                                                                                                                                 |
| 7 to 2       | —        | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 1            | QUE_EN   | Queue Enable<br>Writing 1b to this bit enables the start of processing of descriptor lists registered in the descriptor queue and of DMA transfer (descriptor type). The bit is automatically cleared to 0b when DMA transfer is stopped (normally or abnormally). DMA transfer can also be stopped by writing 0b. However, it is only stopped after the completion of the request (from PCIe or AXI) currently being executed.                                                                                                                  |
| 0            | RDMA_EN  | Register-type DMA Transfer Enable<br>Writing 1b to this bit starts DMA transfer (register type) and transfer specified in the RDMA_SIZE bits proceeds. It is automatically cleared to 0b when DMA has ended in response to the completion of DMA transfer or the detection of an error. DMA transfer can also be stopped by writing 0b. However, it is only stopped after the completion of the request (from PCIe or AXI) currently being executed.<br>1b: Register-type DMA transfer is started.<br>0b: Register-type DMA transfer is stopped. |

**(47) QUE Entry (Lower) Register m (PCI\_RC\_QUEEmL) (m = 0 to 7)**

This register sets the descriptor queue list. This setting value is registered as the DSA (DMA descriptor start address) of the queue list.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0908h (m = 0)  
 <PCI\_S0\_REG\_base> + 0988h (m = 1)  
 <PCI\_S0\_REG\_base> + 0A08h (m = 2)  
 <PCI\_S0\_REG\_base> + 0A88h (m = 3)  
 <PCI\_S0\_REG\_base> + 0B08h (m = 4)  
 <PCI\_S0\_REG\_base> + 0B88h (m = 5)  
 <PCI\_S0\_REG\_base> + 0C08h (m = 6)  
 <PCI\_S0\_REG\_base> + 0C88h (m = 7)

**Initial Value:** 0000\_0000h

Table 35.4-54 PCI\_RC\_QUEEmL Register Contents

| Bit Position | Bit Name                   | Description                                                                                                                                                                                      |
|--------------|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | QUE_ENTRY (DSA)<br>[31:00] | Registers a descriptor list queue. This area becomes the DSA. Set the address where the first descriptor is stored. Since the setting is for 8-byte alignment, the lower 3 bits are fixed to 0b. |

**Note:** When these bits are read, any of the following will be read depending on the state of DMA transfer.

DMA transfer is proceeding: The descriptor list being executed

DMA transfer is stopped (when QUE\_EN has been automatically cleared): The last list to have been executed

DMA transfer is stopped (when QUE\_EN has been cleared by software): The list that has been stopped (during execution).

**(48) QUE Entry (Upper) Register m (PCI\_RC\_QUEEmU) (m = 0 to 7)**

This register sets the descriptor queue list. This setting value is registered as the EI (end interrupt), LS (list stop), and the label of the queue list. Register to the queue by writing to [31:24].

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 090Ch (m = 0)  
 <PCI\_S0\_REG\_base> + 098Ch (m = 1)  
 <PCI\_S0\_REG\_base> + 0A0Ch (m = 2)  
 <PCI\_S0\_REG\_base> + 0A8Ch (m = 3)  
 <PCI\_S0\_REG\_base> + 0B0Ch (m = 4)  
 <PCI\_S0\_REG\_base> + 0B8Ch (m = 5)  
 <PCI\_S0\_REG\_base> + 0C0Ch (m = 6)  
 <PCI\_S0\_REG\_base> + 0C8Ch (m = 7)

**Initial Value:** 0000\_0000h

Table 35.4-55 PCI\_RC\_QUEEmU Register Contents

| Bit Position | Bit Name          | Description                                                                                                                                                                               |
|--------------|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 26     | QUE_Registration  | Register to the queue by writing to [31:24]. The value read is always 0000_00b.                                                                                                           |
| 25           | QUE_ENTRY (EI)    | Specify whether to notify an interrupt (interrupt status CHx_END) when processing of the descriptor list is completed.<br>1b: Notify the interrupt.<br>0b: Does not notify the interrupt. |
| 29           | QUE_ENTRY (LS)    | Specify whether to stop DMA transfer when processing of the descriptor list is completed.<br>1b: Stop DMA transfer.<br>0b: Does not stop DMA transfer.                                    |
| 23 to 16     | —                 | Reserved. These bits are read as 0b.                                                                                                                                                      |
| 15 to 0      | QUE_ENTRY (LABEL) | This field represents the label of the list and there are no special rules for the setting procedures. The value can be set as desired.                                                   |

**Note:** When these bits are read, any of the following will be read depending on the state of DMA transfer.  
 DMA transfer is proceeding: The descriptor list being executed  
 DMA transfer is stopped (when QUE\_EN has been automatically cleared): The last list to have been executed  
 DMA transfer is stopped (when QUE\_EN has been cleared by software): The list that has been stopped (during execution).

**(49) DMA Descriptor Control (Descriptor 00h) Register m (PCI\_RC\_DMADPCTLm) (m = 0 to 7)**

This register indicates the field value at offset 00h in the descriptor table. Only effective when the descriptor-type DMA transfer is selected (the value read has no meaning in the case of register-type transfer).

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0920h (m = 0)  
 <PCI\_S0\_REG\_base> + 09A0h (m = 1)  
 <PCI\_S0\_REG\_base> + 0A20h (m = 2)  
 <PCI\_S0\_REG\_base> + 0AA0h (m = 3)  
 <PCI\_S0\_REG\_base> + 0B20h (m = 4)  
 <PCI\_S0\_REG\_base> + 0BA0h (m = 5)  
 <PCI\_S0\_REG\_base> + 0C20h (m = 6)  
 <PCI\_S0\_REG\_base> + 0CA0h (m = 7)

**Initial Value:** 0000\_0000h

Table 35.4-56 PCI\_RC\_DMADPCTLm Register Contents

| Bit Position | Bit Name | Description                                                             |
|--------------|----------|-------------------------------------------------------------------------|
| 31 to 28     | DSCFM    | Indicates the DSCFM field value in the descriptor table being executed. |
| 27           | —        | Reserved. This bit is read as 0b.                                       |
| 26           | WBD      | Indicates the WBD field value in the descriptor table being executed.   |
| 25           | LE       | Indicates the LE field value in the descriptor table being executed.    |
| 24           | LV       | Indicates the LV field value in the descriptor table being executed.    |
| 23           | D        | Indicates the D field value in the descriptor table being executed.     |
| 22 to 16     | —        | Reserved. These bits are read as 0b.                                    |
| 15 to 0      | STS      | Indicates the STS field value in the descriptor table being executed.   |

(50) DMA Source Address (Descriptor 04h) Register m (PCI\_RC\_DMASRCAm) (m = 0 to 7)

This register sets the start address of the source for DMA transfer.

Table 35.4-57 PCI\_RC\_DMASRCAm Register Contents

| Bit Position | Bit Name   | Description                                                                                                                            |
|--------------|------------|----------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | DMA_S_ADDR | Sets the start address of the source for DMA transfer.<br>Since the setting is for 8-byte alignment, the lower 3 bits are fixed to 0b. |

**Note:** If the source address is for the PCIe space (DIR = 0), the PCIe request address is set in combination with the DMA PCIe upper address (descriptor 10h). When descriptor-type DMA transfer is in process, writing to these bits is prohibited and the value read indicates the value of the SA field in the descriptor table being executed.

(51) DMA Destination Address (Descriptor 08h) Register m (PCI\_RC\_DMADSTAm) (m = 0 to 7)

This register sets the start address of the destination for DMA transfer.

Access Size: 32 bits

Address(es): <PCI\_S0\_REG\_base> + 0928h (m = 0)  
<PCI\_S0\_REG\_base> + 09A8h (m = 1)  
<PCI\_S0\_REG\_base> + 0A28h (m = 2)  
<PCI\_S0\_REG\_base> + 0AA8h (m = 3)  
<PCI\_S0\_REG\_base> + 0B28h (m = 4)  
<PCI\_S0\_REG\_base> + 0BA8h (m = 5)  
<PCI\_S0\_REG\_base> + 0C28h (m = 6)  
<PCI\_S0\_REG\_base> + 0CA8h (m = 7)

Initial Value: 0000\_0000h

Table 35.4-58 PCI\_RC\_DMADSTAm Register Contents

| Bit Position | Bit Name   | Description                                                                                                                                 |
|--------------|------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | DMA_D_ADDR | Sets the start address of the destination for DMA transfer.<br>Since the setting is for 8-byte alignment, the lower 3 bits are fixed to 0b. |

**Note:** If the destination address is for the PCIe space (DIR = 0), the PCIe request address is set in combination with the DMA PCIe upper address (descriptor 10h). When descriptor-type DMA transfer is in process, writing to these bits is prohibited and the value read indicates the value of the DA field in the descriptor table being executed.

(52) DMA Size (Descriptor 0Ch) Register m (PCI\_RC\_DMASIZEm) (m = 0 to 7)

This register sets the number of bytes for DMA transfer. Reflects the field at offset 0Ch in the descriptor table.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 092Ch (m = 0)  
<PCI\_S0\_REG\_base> + 09ACh (m = 1)  
<PCI\_S0\_REG\_base> + 0A2Ch (m = 2)  
<PCI\_S0\_REG\_base> + 0AACh (m = 3)  
<PCI\_S0\_REG\_base> + 0B2Ch (m = 4)  
<PCI\_S0\_REG\_base> + 0BACH (m = 5)  
<PCI\_S0\_REG\_base> + 0C2Ch (m = 6)  
<PCI\_S0\_REG\_base> + 0CACH (m = 7)

Initial Value: 0000\_0000h

Table 35.4-59 PCI\_RC\_DMASIZEm Register Contents

| Bit Position | Bit Name | Description                                                                                                                |
|--------------|----------|----------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | DMA_SIZE | Sets the number of bytes for DMA transfer.<br>Since the setting is for 8-byte alignment, the lower 3 bits are fixed to 0b. |

**Note:** When descriptor-type DMA transfer is in process, writing to these bits is prohibited and the value read indicates the value of the SIZE field in the descriptor table being executed. The number of bytes for transfer when the setting is 0000\_0000h is 1\_0000\_0000h.

(53) DMA PCIe Upper Address (Descriptor 10h) Register m (PCI\_RC\_DMAPCIEUAm) (m = 0 to 7)

This register sets the start address [63:32] for DMA transfer on the PCIe.

Access Size: 32 bits

Address(es): <PCI\_S0\_REG\_base> + 0930h (m = 0)  
<PCI\_S0\_REG\_base> + 09B0h (m = 1)  
<PCI\_S0\_REG\_base> + 0A30h (m = 2)  
<PCI\_S0\_REG\_base> + 0AB0h (m = 3)  
<PCI\_S0\_REG\_base> + 0B30h (m = 4)  
<PCI\_S0\_REG\_base> + 0BB0h (m = 5)  
<PCI\_S0\_REG\_base> + 0C30h (m = 6)  
<PCI\_S0\_REG\_base> + 0CB0h (m = 7)

Initial Value: 0000\_0000h

Table 35.4-60 PCI\_RC\_DMAPCIEUAm Register Contents

| Bit Position | Bit Name    | Description                                                  |
|--------------|-------------|--------------------------------------------------------------|
| 31 to 0      | DMA_PU_ADDR | Sets the start address [63:32] for DMA transfer on the PCIe. |

**Note:** When descriptor-type DMA transfer is in process, writing to these bits is prohibited and the value read indicates the value of the PUA field in the descriptor table being executed.

**(54) DMA Transaction Control (Descriptor 14h) Register m (PCI\_RC\_DMATCTLm) (m = 0 to 7)**

This register controls DMA transfer to the AXI and PCIe.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0934h (m = 0)  
 <PCI\_S0\_REG\_base> + 09B4h (m = 1)  
 <PCI\_S0\_REG\_base> + 0A34h (m = 2)  
 <PCI\_S0\_REG\_base> + 0AB4h (m = 3)  
 <PCI\_S0\_REG\_base> + 0B34h (m = 4)  
 <PCI\_S0\_REG\_base> + 0BB4h (m = 5)  
 <PCI\_S0\_REG\_base> + 0C34h (m = 6)  
 <PCI\_S0\_REG\_base> + 0CB4h (m = 7)

**Initial Value:** 0000\_0000h

| 6 to 4       | DMA_FUNC     | Indicates the request function number issued to PCIe.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 3 to 1       | —            | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

Table 35.4-61 PCI\_RC\_DMATCTLm Register Contents (2/2)

| Bit Position | Bit Name | Description                                                             |
|--------------|----------|-------------------------------------------------------------------------|
| 0            | DMA_DIR  | Sets the direction of DMA transfer.<br>1b: AXI → PCIe<br>0b: PCIe → AXI |

**Note:** When descriptor-type DMA transfer is in process, writing to these bits is prohibited and the value read indicates the value of the CCH\_L, CCH\_D, TC, ATB, and DIR fields in the descriptor table being executed.

(55) DMA Descriptor Link Pointer (Descriptor 1Ch) Register m (PCI\_RC\_DMADPLPm) (m = 0 to 7)

This register indicates the field value at offset 1Ch in the descriptor table. Only effective when the descriptor-type DMA transfer is selected (the value read has no meaning in the case of register-type transfer).

Access Size: 32 bits

Address(es): <PCI\_S0\_REG\_base> + 093Ch (m = 0)  
<PCI\_S0\_REG\_base> + 09BCh (m = 1)  
<PCI\_S0\_REG\_base> + 0A3Ch (m = 2)  
<PCI\_S0\_REG\_base> + 0ABCh (m = 3)  
<PCI\_S0\_REG\_base> + 0B3Ch (m = 4)  
<PCI\_S0\_REG\_base> + 0BBCh (m = 5)  
<PCI\_S0\_REG\_base> + 0C3Ch (m = 6)  
<PCI\_S0\_REG\_base> + 0CBCh (m = 7)

Initial Value: 0000\_0000h

| Bit Position | Bit Name | Description                                                          |
|--------------|----------|----------------------------------------------------------------------|
| 31 to 0      | DMA_LP   | Indicates the LP field value in the descriptor table being executed. |

(56) DMA Rest Size Register m (PCI\_RC\_DMARESTSIZm) (m = 0 to 7)

This register indicates the number of bytes for which DMA transfer has not yet been completed.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0950h (m = 0)  
<PCI\_S0\_REG\_base> + 09D0h (m = 1)  
<PCI\_S0\_REG\_base> + 0A50h (m = 2)  
<PCI\_S0\_REG\_base> + 0AD0h (m = 3)  
<PCI\_S0\_REG\_base> + 0B50h (m = 4)  
<PCI\_S0\_REG\_base> + 0BD0h (m = 5)  
<PCI\_S0\_REG\_base> + 0C50h (m = 6)  
<PCI\_S0\_REG\_base> + 0CD0h (m = 7)

Initial Value: 0000\_0000h

Table 35.4-63 PCI\_RC\_DMARESTSIZm Register Contents

| Bit Position | Bit Name      | Description                                                                                                                             |
|--------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | DMA_REST_SIZE | Indicates the number of bytes for which DMA transfer has not yet been completed (common to register-type and descriptor-type transfer). |

(57) AXI Request Address Register m (PCI\_RC\_AREQAm) (m = 0 to 7)

This register indicates the address during AXI transfer that is in progress or for the most recently completed transfer.

Access Size: 32 bits

Address(es): <PCI\_S0\_REG\_base> + 0954h (m = 0)  
<PCI\_S0\_REG\_base> + 09D4h (m = 1)  
<PCI\_S0\_REG\_base> + 0A54h (m = 2)  
<PCI\_S0\_REG\_base> + 0AD4h (m = 3)  
<PCI\_S0\_REG\_base> + 0B54h (m = 4)  
<PCI\_S0\_REG\_base> + 0BD4h (m = 5)  
<PCI\_S0\_REG\_base> + 0C54h (m = 6)  
<PCI\_S0\_REG\_base> + 0CD4h (m = 7)

Initial Value: 0000\_0000h

Table 35.4-64 PCI\_RC\_AREQAm Register Contents

| Bit Position | Bit Name     | Description                                                                                                                                              |
|--------------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | AXI_REQ_ADDR | Indicates the address during AXI transfer that is in progress or for the most recently completed transfer (common to register type and descriptor type). |

(58) PCIe Request Address (Lower) Register m (PCI\_RC\_PREQAmL) (m = 0 to 7)

This register indicates the lower 32 bits of the address during PCIe transfer that is in progress or for the most recently completed transfer.

Access Size: 32 bits

Address(es): <PCI\_S0\_REG\_base> + 0958h (m = 0)  
<PCI\_S0\_REG\_base> + 09D8h (m = 1)  
<PCI\_S0\_REG\_base> + 0A58h (m = 2)  
<PCI\_S0\_REG\_base> + 0AD8h (m = 3)  
<PCI\_S0\_REG\_base> + 0B58h (m = 4)  
<PCI\_S0\_REG\_base> + 0BD8h (m = 5)  
<PCI\_S0\_REG\_base> + 0C58h (m = 6)  
<PCI\_S0\_REG\_base> + 0CD8h (m = 7)

Initial Value: 0000\_0000h

Table 35.4-65 PCI\_RC\_PREQAmL Register Contents

| Bit Position | Bit Name      | Description                                                                                                                                                                    |
|--------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | PCIE_REQ_ADDR | Indicates the lower 32 bits of the address during PCIe transfer that is in progress or for the most recently completed transfer (common to register type and descriptor type). |

(59) PCIe Request Address (Upper) Register m (PCI\_RC\_PREQAmU) (m = 0 to 7)

This register indicates the upper 32 bits of the address during PCIe transfer that is in progress or for the most recently completed transfer.

Access Size: 32 bits

Address(es): <PCI\_S0\_REG\_base> + 095Ch (m = 0)  
<PCI\_S0\_REG\_base> + 09DCh (m = 1)  
<PCI\_S0\_REG\_base> + 0A5Ch (m = 2)  
<PCI\_S0\_REG\_base> + 0ADCh (m = 3)  
<PCI\_S0\_REG\_base> + 0B5Ch (m = 4)  
<PCI\_S0\_REG\_base> + 0BDCh (m = 5)  
<PCI\_S0\_REG\_base> + 0C5Ch (m = 6)  
<PCI\_S0\_REG\_base> + 0CDCh (m = 7)

Initial Value: 0000\_0000h

Table 35.4-66 PCI\_RC\_PREQAmU Register Contents

| Bit Position | Bit Name      | Description                                                                                                                                                                    |
|--------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | PCIE_REQ_ADDR | Indicates the upper 32 bits of the address during PCIe transfer that is in progress or for the most recently completed transfer (common to register type and descriptor type). |

**(60) QUE Status Register m (PCI\_RC\_QUESTAm) (m = 0 to 7)**

This register indicates the state of the descriptor queue.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0960h (m = 0)  
 <PCI\_S0\_REG\_base> + 09E0h (m = 1)  
 <PCI\_S0\_REG\_base> + 0A60h (m = 2)  
 <PCI\_S0\_REG\_base> + 0AE0h (m = 3)  
 <PCI\_S0\_REG\_base> + 0B60h (m = 4)  
 <PCI\_S0\_REG\_base> + 0BE0h (m = 5)  
 <PCI\_S0\_REG\_base> + 0C60h (m = 6)  
 <PCI\_S0\_REG\_base> + 0CE0h (m = 7)

**Initial Value:** 0000\_0000h

Table 35.4-67 PCI\_RC\_QUESTAm Register Contents

| Bit Position | Bit Name | Description                                                                                                                                                                                                                                                                                                                          |
|--------------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 5      | —        | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                 |
| 4            | GO_LIST  | Indicates whether a descriptor list being executed is or is not present.<br>1b: Present<br>0b: Not present                                                                                                                                                                                                                           |
| 3 to 0       | LIST_NUM | Indicates the number of descriptor lists with which the queue for the given DMA channel has been loaded (any list currently being executed is not included). Attempts at making new entries in the queue while the value of this field is 8 (writing to the queue entry bits for the given channel) has no effect (will be ignored). |

**(61) DMAC Error Status Register m (PCI\_RC\_DMACESTAm) (m = 0 to 7)**

This register indicates the error status of the DMAC.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0968h (m = 0)  
 <PCI\_S0\_REG\_base> + 09E8h (m = 1)  
 <PCI\_S0\_REG\_base> + 0A68h (m = 2)  
 <PCI\_S0\_REG\_base> + 0AE8h (m = 3)  
 <PCI\_S0\_REG\_base> + 0B68h (m = 4)  
 <PCI\_S0\_REG\_base> + 0BE8h (m = 5)  
 <PCI\_S0\_REG\_base> + 0C68h (m = 6)  
 <PCI\_S0\_REG\_base> + 0CE8h (m = 7)

**Initial Value:** 0000\_0000h

**(62) AXI Window Base m Register (PCI\_RC\_AWBASEm) (m = 0 to 7)**

This register is for setting windows for address conversion in access from PCIe to AXI. It sets the base address on the PCI. The areas are set in 4-Kbyte boundaries.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 1000h (m = 0)  
 <PCI\_S0\_REG\_base> + 1010h (m = 1)  
 <PCI\_S0\_REG\_base> + 1020h (m = 2)  
 <PCI\_S0\_REG\_base> + 1030h (m = 3)  
 <PCI\_S0\_REG\_base> + 1040h (m = 4)  
 <PCI\_S0\_REG\_base> + 1050h (m = 5)  
 <PCI\_S0\_REG\_base> + 1060h (m = 6)  
 <PCI\_S0\_REG\_base> + 1070h (m = 7)

**Initial Value:** 0000\_0000h

| 31           | —             | Reserved. This bit is read as 0b.                                                                                                                    |
| 30 to 12     | PWMask[30:12] | The window is set as the area corresponding to the number of set bits from the address set in the PWBase register. Set 1b from the lowest-order bit. |
| 11 to 0      | PWMask[11:0]  | Fixed to 1111_1111_1111b.                                                                                                                            |

(67) PCIe Destination m (Lower) Register (PCI\_RC\_PDESTLOm) (m = 0 to 7)

This register is for setting windows for address conversion in access from AXI to PCIe. The base address of the window in the address space on the AXI is set. The areas are set in 4-Kbyte boundaries.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 1108h (m = 0)  
<PCI\_S0\_REG\_base> + 1118h (m = 1)  
<PCI\_S0\_REG\_base> + 1128h (m = 2)  
<PCI\_S0\_REG\_base> + 1138h (m = 3)  
<PCI\_S0\_REG\_base> + 1148h (m = 4)  
<PCI\_S0\_REG\_base> + 1158h (m = 5)  
<PCI\_S0\_REG\_base> + 1168h (m = 6)  
<PCI\_S0\_REG\_base> + 1178h (m = 7)

**Initial Value:** 0000\_0000h

Table 35.4-74 PCI\_RC\_PDESTLOm Register Contents

| Bit Position | Bit Name     | Description                                                                                                    |
|--------------|--------------|----------------------------------------------------------------------------------------------------------------|
| 31 to 12     | PDest[31:12] | The base address of the window in the address base on the AXI is set. The areas are set in 4-Kbyte boundaries. |
| 11 to 0      | PDest[11:0]  | Fixed to 0000_0000_0000b.                                                                                      |

(68) PCIe Destination m (Upper) Register (PCI\_RC\_PDESTUPm) (m = 0 to 7)

This register is for setting windows for address conversion in access from AXI to PCIe. The base address of the window in the address space on the AXI is set. The areas are set in 4-Kbyte boundaries.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 110Ch (m = 0)  
<PCI\_S0\_REG\_base> + 111Ch (m = 1)  
<PCI\_S0\_REG\_base> + 112Ch (m = 2)  
<PCI\_S0\_REG\_base> + 113Ch (m = 3)  
<PCI\_S0\_REG\_base> + 114Ch (m = 4)  
<PCI\_S0\_REG\_base> + 115Ch (m = 5)  
<PCI\_S0\_REG\_base> + 116Ch (m = 6)  
<PCI\_S0\_REG\_base> + 117Ch (m = 7)

**Initial Value:** 0000\_0000h

Table 35.4-75 PCI\_RC\_PDESTUPm Register Contents

| Bit Position | Bit Name     | Description                                                                                                    |
|--------------|--------------|----------------------------------------------------------------------------------------------------------------|
| 31 to 0      | PDest[63:32] | The base address of the window in the address base on the AXI is set. The areas are set in 4-Kbyte boundaries. |

35.4.3.2 PCI Express Configuration Registers (Type1)

(1) Vendor and Device ID Register (PCI\_RC\_VID)

This register indicates the vendor and device ID. This register can be written during initialization.

Table 35.4-76 PCI\_RC\_VID Register Contents

| Bit Position | Bit Name  | Description                                                                                              |
|--------------|-----------|----------------------------------------------------------------------------------------------------------|
| 31 to 16     | Device ID | Indicates the manufacturer. Set a fixed value.                                                           |
| 15 to 0      | Vendor ID | Used to identify devices manufactured by the manufacturer indicated by the vendor ID. Set a fixed value. |

Table 35.4-77 Valid Reset Signal

| Reset Signal | Device ID | Vendor ID |
|--------------|-----------|-----------|
| RST_LOAD_B   | ✓         | ✓         |
| RST_RSM_B    |           |           |
| RST_CFG_B    |           |           |

**(2) Command and Status Register (PCI\_RC\_COM\_STA)**

This register specifies the command and the status.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 6004h

**Initial Value:** 0010\_0000h

| Bit           | 31                    | 30                    | 29                    | 28                    | 27                    | 26            | 25 | 24                       | 23 | 22 | 21 | 20                | 19               | 18 | 17 | 16                  |

(6) Base Address Register 1 (PCI\_RC\_BAR1)

This register forms a 64-bit memory space in combination with Base Address Register 0 (BAR0).

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 6014h  
Initial Value: 0000\_0000h

Table 35.4-86 PCI\_RC\_BAR1 Register Contents

| Bit Position | Bit Name                | Description                                                                                        |

(7) Capabilities Pointer Register (PCI\_RC\_CP)

This register indicates the I/O base, limit, and secondary status.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 6034h  
Initial Value: 0000\_0040h

**(11) PCI Express Capability Register (PCI\_RC\_PCIEC)**

This register indicates the PCIe capability.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 6060h

**Initial Value:** 0042\_0010h

| Bit           | 31                      | 30     | 29                       | 28     | 27     | 26     | 25     | 24               | 23               | 22 | 21 | 20 | 19                 | 18     | 17     | 16     |

**(12) Device Capabilities Register (PCI\_RC\_DEVC)**

This register indicates the device capability.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 6064h

**Initial Value:** 0000\_8000h

| Bit           | 31                         | 30 | 29 | 28                              | 27                              | 26 | 25                              | 24                              | 23 | 22 | 21                           | 20                          | 19 | 18                         | 17 | 16 |   |

**(14) Link Capabilities Register (PCI\_RC\_LINKC)**

This register indicates the link capabilities. This register can be written during initialization.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 606Ch

**Initial Value:** 0073\_6C22h

**(15) Link Control/Status Register (PCI\_RC\_LINKCS)**

This register controls the link and indicates the link status.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 6070h

**Initial Value:** 1000\_0008h

**(16) Device Capabilities 2 Register (PCI\_RC\_DEVC2)**

This register indicates the device capability.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 6084h

**Initial Value:** 0000\_0012h

| Bit           | 31 | 30 | 29 | 28 | 27                      | 26                                                | 25                                  | 24 | 23 | 22 | 21 | 20                                   | 19                                  | 18     | 17                             | 16                             |

| 25 to 16     | Base Size 01 | Fixed to 00_0000_0000b.<br>Not used.<br>This register can be written during initialization.                                                                                                                                                                                                                                                                                                                                                                              |
| 15 to 10     | —            | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 9 to 0       | Base Size 00 | Sets the size of the TLP (DW size) which can be accepted by Address Space 00 set by the Base Address Register and Base Address Mask Register. When a TLP with a packet length greater than the size set in these bits is received, even if it is smaller than the max payload size, a completer abort error (CA) is detected. Note that the initial value is 0_0000_0000b and this function is invalid in this case. This register can be written during initialization. |

Table 35.4-127 Valid Reset Signal

**(34) Uncorrectable Error Severity Register (PCI\_RC\_UNCESVY)**

This register sets the uncorrectable error severity.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 610Ch

**Initial Value:** 0046\_2030h

| Bit           | 31                       | 30                          | 29                                   | 28                             | 27 | 26 | 25 | 24 | 23 | 22     | 21                           | 20                                 | 19                  | 18                     | 17                         | 16                             |

Table 35.4-148 PCI\_RC\_ADVECC Register Contents

| Bit Position | Bit Name                | Description                                                                                                                        |
|--------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 9      | —                       | Reserved. These bits are read as 0b.                                                                                               |
| 8            | ECRC Check Enable       | Enables ECRC checking.<br>0b: Disable (initial value)<br>1b: Enable                                                                |
| 7            | ECRC Check Capable      | Indicates whether ECRC checking is implemented.<br>0b: No ECRC checking<br>1b: ECRC checking is implemented (initial value).       |
| 6            | ECRC Generation Enable  | Enables ECRC generation.<br>0b: Disable (initial value)<br>1b: Enable                                                              |
| 5            | ECRC Generation Capable | Indicates whether ECRC generation is implemented.<br>0b: No ECRC generation<br>1b: ECRC generation is implemented (initial value). |
| 4 to 0       | First Error Pointer     | Indicates the field value of the Uncorrectable Error Status register for the first uncorrectable error detection.                  |

**Note:** The First Error Pointer bits [4:0] are reset by RST\_GP\_B.

Table 35.4-149 Valid Reset Signal

| Reset Signal | ECRC Check Enable | ECRC Generation Enable |
|--------------|-------------------|------------------------|
| RST_LOAD_B   |                   |                        |
| RST_RSM_B    | ✓                 | ✓                      |
| RST_CFG_B    |                   |                        |

(38) Header Log Register 0 (PCI\_RC\_HLOG0)

This register indicates the header log.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 611Ch  
Initial Value: 0000\_0000h

Table 35.4-150 PCI\_RC\_HLOG0 Register Contents

| Bit Position | Bit Name                              | Description                                                                          |
|--------------|---------------------------------------|--------------------------------------------------------------------------------------|
| 31 to 0      | Header of TLP associated with error 0 | Indicates the 1st DW of the header where the first uncorrectable error was detected. |

(39) Header Log Register 1 (PCI\_RC\_HLOG1)

This register indicates the header log.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 6120h  
Initial Value: 0000\_0000h

Table 35.4-151 PCI\_RC\_HLOG1 Register Contents

| Bit Position | Bit Name                              | Description                                                                          |
|--------------|---------------------------------------|--------------------------------------------------------------------------------------|
| 31 to 0      | Header of TLP associated with error 1 | Indicates the 2nd DW of the header where the first uncorrectable error was detected. |

(40) Header Log Register 2 (PCI\_RC\_HLOG2)

This register indicates the header log.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 6124h  
Initial Value: 0000\_0000h

Table 35.4-152 PCI\_RC\_HLOG2 Register Contents

| Bit Position | Bit Name                              | Description                                                                          |
|--------------|---------------------------------------|--------------------------------------------------------------------------------------|
| 31 to 0      | Header of TLP associated with error 2 | Indicates the 3rd DW of the header where the first uncorrectable error was detected. |

(41) Header Log Register 3 (PCI\_RC\_HLOG3)

This register indicates the header log.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 6128h  
Initial Value: 0000\_0000h

Table 35.4-153 PCI\_RC\_HLOG3 Register Contents

| Bit Position | Bit Name                              | Description                                                                          |
|--------------|---------------------------------------|--------------------------------------------------------------------------------------|
| 31 to 0      | Header of TLP associated with error 3 | Indicates the 4th DW of the header where the first uncorrectable error was detected. |

(42) Device Serial Number Extended Capability Register (PCI\_RC\_DEVSNEXTC)

This register specifies the device serial number extended capability.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 6150h  
Initial Value: 0001\_0003h

| Bit           | 31                                 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19                 | 18     | 17     | 16     |

| Bit Position | Bit Name                           | Description                                                                                                                            |
|--------------|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 20     | Next Capability Offset             | Indicates that this is the last item in the capability list.<br>Fixed to 000h.                                                         |
| 19 to 16     | Capability Version                 | Indicates the version number of the capability structure.<br>Initial value: 0001b. This register can be written during initialization. |
| 15 to 0      | PCI Express Extended Capability ID | Indicates the device serial number extended capability.<br>Initial value: 0003h                                                        |

Table 35.4-155 Valid Reset Signal

| Reset Signal | Next Capability Offset | Capability Version |
|--------------|------------------------|--------------------|
| RST_LOAD_B   | ✓                      | ✓                  |
| RST_RSM_B    |                        |                    |
| RST_CFG_B    |                        |                    |

(43) Serial Number Register (Lower DW) (PCI\_RC\_SNL)

This register specifies the serial number of the device.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 6154h  
Initial Value: 0000\_0000h

Table 35.4-156 PCI\_RC\_SNL Register Contents

| Bit Position | Bit Name                                    | Description                                                                                                                                                                                                                     |
|--------------|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | PCI Express Device Serial Number (Lower DW) | These are the lower-order 32 bits of a unique ID (EUI-64) of the IEEE specification. An EUI-64 consists of a 24-bit company ID and a 40-bit vendor-defined extension ID.<br>This register can be written during initialization. |

Table 35.4-157 Valid Reset Signal

| Reset Signal | PCI Express Device Serial Number (Lower DW) |
|--------------|---------------------------------------------|
| RST_LOAD_B   | ✓                                           |
| RST_RSM_B    |                                             |
| RST_CFG_B    |                                             |

(44) Serial Number Register (Upper DW) (PCI\_RC\_SNU)

This register specifies the serial number of the device.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 6158h  
Initial Value: 0000\_0000h

Table 35.4-158 PCI\_RC\_SNU Register Contents

| Bit Position | Bit Name                                    | Description                                                                                                                                                                                                                      |
|--------------|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | PCI Express Device Serial Number (Upper DW) | These are the higher-order 32 bits of a unique ID (EUI-64) of the IEEE specification. An EUI-64 consists of a 24-bit company ID and a 40-bit vendor-defined extension ID.<br>This register can be written during initialization. |

Table 35.4-159 Valid Reset Signal

| Reset Signal | PCI Express Device Serial Number (Upper DW) |
|--------------|---------------------------------------------|
| RST_LOAD_B   | ✓                                           |
| RST_RSM_B    |                                             |
| RST_CFG_B    |                                             |

### 35.5 Register Descriptions (Endpoint Mode)

The following lists the registers incorporated in the unit.  
For the register base address (<PCI\_S0\_REG\_base>), see the section of Address Map.

CAUTION

The results of access to reserved bit areas, debug bit areas, and undefined areas are not guaranteed. The combination of reserved, debug, and undefined areas includes cases where the initial values will be non-zero, and the results of changes to such values are not guaranteed.

The following is the outline of categories of the register space within this unit.

|                                             |                                                 |
|---------------------------------------------|-------------------------------------------------|
| AXI Bridge Registers                        | <PCI_S0_REG_base> + 0000h-1FFCh                 |
| Reserved                                    | <PCI_S0_REG_base> + 2000h-5FFCh                 |
| PCI Express Configuration Registers (Type0) | <PCI_S0_REG_base> + 6000h-6FFCh ( Function #0 ) |
| PCI Express Configuration Registers (Type0) | <PCI_S0_REG_base> + 7000h-7FFCh ( Function #1 ) |

Access to the reserved spaces above is prohibited.

### 35.5.1 List of AXI Bridge Registers

Unless specifically stated otherwise, byte, word, and double word access are all possible.

Access to registers is possible from the AXI-bus side and the PCIe-bus side. Attributes may vary with the register and the direction of access. In the case of registers for which attributes vary, attributes in the upper parts of the cells in the R/W column are for access from the PCIe-bus side and those in the lower parts are for access from the AXI-bus side. However, the cells are not divided into upper and lower parts in cases where access does not vary with the side proceeding with access.

Table 35.5-1 AXI Bridge Registers (1/6)

| Offset Address                    | Register Name                              | Abbreviation     | Initial Value | Access Unit (bits) |
|-----------------------------------|--------------------------------------------|------------------|---------------|--------------------|
| Reserved 00h to 7Ch               |                                            |                  |               |                    |
| 00 to 7Ch                         | Reserved                                   | —                | —             | —                  |
| Request Issuing 80h to FCh        |                                            |                  |               |                    |
| 80h                               | Request Data Register 0                    | PCI_EP_REQDATA0  | xxxx_xxxxh    | 32                 |
| 84h                               | Request Data Register 1                    | PCI_EP_REQDATA1  | xxxx_xxxxh    | 32                 |
| 88h                               | Request Data Register 2                    | PCI_EP_REQDATA2  | xxxx_xxxxh    | 32                 |
| 8Ch                               | Request Receive Data Register              | PCI_EP_REQRCVDAT | xxxx_xxxxh    | 32                 |
| 90h                               | Request Address Register 1                 | PCI_EP_REQADR1   | xxxx_xxxxh    | 32                 |
| 94h                               | Request Address Register 2                 | PCI_EP_REQADR2   | xxxx_xxxxh    | 32                 |
| 98h                               | Request Byte Enable Register               | PCI_EP_REQBE     | 0000_000Fh    | 32                 |
| 9Ch                               | Request Issue Register                     | PCI_EP_REQISS    | 0000_0000h    | 32                 |
| A0 to FCh                         | Reserved                                   | —                | —             | —                  |
| PCI Interruption 100h to 11Ch     |                                            |                  |               |                    |
| 100h to 114h                      | Reserved                                   | —                | —             | —                  |
| 118h                              | PCI INTx Out Status Register               | PCI_EP_INTXOUTS  | 0000_0000h    | 32                 |
| 11Ch                              | Reserved                                   | —                | —             | —                  |
| Message Interruption 120h to 13Ch |                                            |                  |               |                    |
| 120h                              | Message Receive Interrupt Enable Register  | PCI_EP_MSGRCVIE  | 0000_0000h    | 32                 |
| 124h                              | Message Receive Interrupt Status Register  | PCI_EP_MSGRCVIS  | 0000_0000h    | 32                 |
| 128h to 12Ch                      | Reserved                                   | —                | —             | —                  |
| 130h                              | Message Code Register                      | PCI_EP_MSGCODE   | 0000_0000h    | 32                 |
| 134h                              | Message Data Register                      | PCI_EP_MSGDATA   | 0000_0000h    | 32                 |
| 138h                              | Message Header 3rdDW Register              | PCI_EP_MSGH3DW   | 0000_0000h    | 32                 |
| 13Ch                              | Message Header 4thDW Register              | PCI_EP_MSGH4DW   | 0000_0000h    | 32                 |
| Interrupt Table 140h to 1FCh      |                                            |                  |               |                    |
| 140h                              | Interrupt Table Register                   | PCI_EP_INTTABLE  | 00xx_0000h    | 32                 |
| 144h to 1FCh                      | Reserved                                   | —                | —             | —                  |
| Error Event 200h to 2FCh          |                                            |                  |               |                    |
| 200h                              | PCIe Event Interrupt Enable 0 Register     | PCI_EP_PEIE0     | 0000_0000h    | 32                 |
| 204h                              | PCIe Event Interrupt Status 0 Register     | PCI_EP_PEIS0     | 0000_0000h    | 32                 |
| 208h                              | PCIe Event Interrupt Enable 1 Register     | PCI_EP_PEIE1     | 0000_0000h    | 32                 |
| 20Ch                              | PCIe Event Interrupt Status 1 Register     | PCI_EP_PEIS1     | 0000_0000h    | 32                 |
| 210h                              | AXI Master Error Interrupt Enable Register | PCI_EP_AMEIE     | 0000_0000h    | 32                 |
| 214h                              | AXI Master Error Interrupt Status Register | PCI_EP_AMEIS     | 0000_0000h    | 32                 |
| 218h to 21Ch                      | Reserved                                   | —                | —             | —                  |

Table 35.5-1 AXI Bridge Registers (2/6)

| Offset Address              | Register Name                               | Abbreviation      | Initial Value | Access Unit (bits) |
|-----------------------------|---------------------------------------------|-------------------|---------------|--------------------|
| 220h                        | AXI Slave Error Interrupt Enable 1 Register | PCI_EP_ASEIE1     | 0000_0000h    | 32                 |
| 224h                        | AXI Slave Error Interrupt Status 1 Register | PCI_EP_ASEIS1     | 0000_0000h    | 32                 |
| 228h to 22Ch                | Debug                                       | —                 | —             | —                  |
| 230h                        | AXI Slave Error Interrupt Status 3 Register | PCI_EP_ASEIS3     | 0000_0000h    | 32                 |
| 234h                        | Debug                                       | —                 | —             | —                  |
| 238h to 23Ch                | Reserved                                    | —                 | —             | —                  |
| 240h                        | PCIe Event Interrupt Enable 2 Register      | PCI_EP_PEIE2      | 0000_0000h    | 32                 |
| 244h                        | PCIe Event Interrupt Status 2 Register      | PCI_EP_PEIS2      | 0000_0000h    | 32                 |

| 1368h          | PCIe Destination 6 (Lower) Register (Function #1) | PCI_EP_PDESTLO6_F1 | 0000_0000h    | 32                 |
| 136Ch          | PCIe Destination 6 (Upper) Register (Function #1) | PCI_EP_PDESTUP6_F1 | 0000_0000h    | 32                 |
| 1370h          | PCIe Window Base 7 Register (Function #1)         | PCI_EP_PWBASE7_F1  | 0000_0000h    | 32                 |
| 1374h          | PCIe Window Mask 7 Register (Function #1)         | PCI_EP_PWMASK7_F1  | 0000_0FFFh    | 32                 |
| 1378h          | PCIe Destination 7 (Lower) Register (Function #1) | PCI_EP_PDESTLO7_F1 | 0000_0000h    | 32                 |
| 137Ch          | PCIe Destination 7 (Upper) Register (Function #1) | PCI_EP_PDESTUP7_F1 | 0000_0000h    | 32                 |
| 1380h to 1FFCh | Reserved                                          | —                  | —             | —                  |

**Note:** Debug: Registers for use in debugging by Renesas. Access to these registers may lead to a malfunction.

Reserved: Reserved registers. The results of access to these registers and operation of the core through such access are not guaranteed.

Note 1. The addresses listed in the above table are those for channel 0. These addresses should be read as the addresses for the other DMAC channels according to the table below.

| Channel Offset Address |           |
|------------------------|-----------|
| offset + 000h          | Channel 0 |
| offset + 080h          | Channel 1 |
| offset + 100h          | Channel 2 |
| offset + 180h          | Channel 3 |
| offset + 200h          | Channel 4 |
| offset + 280h          | Channel 5 |
| offset + 300h          | Channel 6 |
| offset + 380h          | Channel 7 |

Example)

Channel 0: DMA Descriptor Control Register (offset: 920h = 920h + 000h)

Channel 1: DMA Descriptor Control Register (offset: 9A0h = 920h + 080h)

Channel 2: DMA Descriptor Control Register (offset: A20h = 920h + 100h)

Channel 3: DMA Descriptor Control Register (offset: AA0h = 920h + 180h)

Channel 4: DMA Descriptor Control Register (offset: B20h = 920h + 200h)

Channel 5: DMA Descriptor Control Register (offset: BA0h = 920h + 280h)

Channel 6: DMA Descriptor Control Register (offset: C20h = 920h + 300h)

Channel 7: DMA Descriptor Control Register (offset: CA0h = 920h + 380h)

Note 2. The register functions for function 1 is the same as those for function 0, so refer to the functions for function 0 for details of the register functions.

## 35.5.2 List of PCI Express Configuration Registers

### 35.5.2.1 Type 0 (for Endpoint)

**Table 35.5-2** lists the PCI Express configuration registers (Type 0).

Table 35.5-2 PCI Express Configuration Registers (Type0) (1/4)

| Offset Address                            | Register Name                                          | Abbreviation      | Initial Value | Access Unit (bits) |
|-------------------------------------------|--------------------------------------------------------|-------------------|---------------|--------------------|
| Common Configuration Space                |                                                        |                   |               |                    |
| 6000h                                     | Vendor and Device ID (Function #0)* <sup>1</sup>       | PCI_EP_VID_F0     | 0000_0000h    | 32                 |
| 6004h                                     | Command and Status (Function #0)                       | PCI_EP_COM_STA_F0 | 0010_0000h    | 32                 |
| 6008h                                     | Revision ID and Class Code (Function #0)* <sup>1</sup> | PCI_EP_RID_CC_F0  | 0000_0000h    | 32                 |
| 600Ch                                     | Cache Line and Header Type (Function #0)               | PCI_EP_CL_HT_F0   | 0080_0000h    | 32                 |
| Configuration Space                       |                                                        |                   |               |                    |
| 6010h                                     | Base Address Register 0 (Function #0)                  | PCI_EP_BAR0_F0    | 0000_0004h    | 32                 |
| 6014h                                     | Base Address Register 1 (Function #0)                  | PCI_EP_BAR1_F0    | 0000_0000h    | 32                 |
| 6018h                                     | Base Address Register 2 (Function #0)                  | PCI_EP_BAR2_F0    | 0000_0004h    | 32                 |

**Note:** “Specific Registers” refer to the registers specific to this unit. They cannot be controlled from the root complex. When the values need to be changed from the initial values, they must be set from the CPU, etc. of the endpoint before the link is up.

Note 1. Set the initial value from the local CPU, etc.

### 35.5.3 Register Descriptions (Endpoint Mode)

#### 35.5.3.1 AXI Bridge Registers

The function of each register is described below.

Registers can be accessed from the AXI and PCIe. Depending on the register, the attributes change depending on the access direction. The upper row of the of R/W shows the R/W when accessing from the PCIe and the lower row shows the R/W when accessing from the AXI. If the access from either side does not change, it is not divided into upper and lower rows.

##### (1) Request Data Register m (PCI\_EP\_REQDATAm) (m = 0 to 2)

This register issues various requests. Write access to this register is only possible from AXI. In case of write access from PCIe, it returns a response and ends normally without writing data to this register. Read access is possible from both AXI and PCIe.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0080h (m = 0)

<PCI\_S0\_REG\_base> + 0084h (m = 1)

<PCI\_S0\_REG\_base> + 0088h (m = 2)

**Initial Value:** xxxx\_xxxxh

Table 35.5-3 PCI\_EP\_REQDATAm Register Contents

| Bit Position | Bit Name     | Description                            |
|--------------|--------------|----------------------------------------|
| 31 to 0      | Request Data | Sets write data for issuing a request. |

Table 35.5-4 Valid Reset Signal

|                                   | Request Data Register 0 | Request Data Register 1 | Request Data Register 2 |
|-----------------------------------|-------------------------|-------------------------|-------------------------|
| Zero-Length Read Request          | Invalid                 | Invalid                 | Invalid                 |
| Message Request                   | 3rd header              | 4th header              | Invalid                 |
| Message Request with data payload | 3rd header              | 4th header              | Message data            |

**Note:** The bits should be set to 0 for the requests indicated as "Invalid".

(2) Request Receive Data Register (PCI\_EP\_REQRCVDAT)

This register indicates the data read on reception of the completion response after issuing a read request.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 008Ch  
Initial Value: xxxx\_xxxxh

|               |                      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|---------------|----------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

Table 35.5-5 PCI\_EP\_REQRCVDAT Register Contents

| Bit Position | Bit Name             | Description                                                                                                                                                        |
|--------------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | Request Receive Data | After issuing a read request, the data read on reception of the completion response are set in these bits. However, these bits are invalid for each write request. |

(3) Request Address Register 1 (PCI\_EP\_REQADR1)

This register issues requests. Write access to this register is only possible from AXI. In case of write access from PCIe, it returns a response and ends normally without writing data to this register. Read access is possible from both AXI and PCIe.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0090h  
Initial Value: xxxx\_xxxxh

Table 35.5-6 PCI\_EP\_REQADR1 Register Contents

| Bit Position | Bit Name               | Description                             |
|--------------|------------------------|-----------------------------------------|
| 31 to 0      | Request Address [31:0] | Sets the address for issuing a request. |

Table 35.5-7 Valid Reset Signal

| Request Address Register 1        | [31:27]  | [26:24]      | [23:19]  | [18:16]  |
|-----------------------------------|----------|--------------|----------|----------|
| Zero-Length Read Request          | Address  |              |          |          |
| Message Request                   | Reserved | Routing Type | Reserved | Reserved |
| Message Request with data payload | Reserved | Routing Type | Reserved | Reserved |

  

| Request Address Register 1        | [15:12]  | [11:8]   | [7:2]        | [1:0]    |
|-----------------------------------|----------|----------|--------------|----------|
| Zero-Length Read Request          | Address  |          |              | Reserved |
| Message Request                   | Reserved | Reserved | Message Code |          |
| Message Request with data payload | Reserved | Reserved | Message Code |          |

**Note:** The bits should be set to 0 for the requests indicated as “Reserved”.

(4) Request Address Register 2 (PCI\_EP\_REQADR2)

This register issues requests. Write access to this register is only possible from AXI. In case of write access from PCIe, it returns a response and ends normally without writing data to this register. Read access is possible from both AXI and PCIe.

Table 35.5-8 PCI\_EP\_REQADR2 Register Contents

| Bit Position | Bit Name                | Description                             |
|--------------|-------------------------|-----------------------------------------|
| 31 to 0      | Request Address [63:32] | Sets the address for issuing a request. |

Table 35.5-9 Valid Reset Signal

|                                   | [31:0]  |
|-----------------------------------|---------|
| Zero-Length Read Request          | Address |
| Message Request                   | Invalid |
| Message Request with data payload | Invalid |

**Note:** The bits should be set to 0 for the requests indicated as "Invalid".

(5) Request Byte Enable Register (PCI\_EP\_REQBE)

This register specifies the first byte enable bit within the TLP header (1st DW byte) when issuing a request to PCIe. Write access to this register is only possible from AXI. In case of write access from PCIe, it returns a response and ends normally without writing data to this register. Read access is possible from both AXI and PCIe.

Access Size: 32 bits

**(7) PCI INTx Out Status Register (PCI\_EP\_INTXOUTS)**

This register can confirm the PCI INTx status issued by the unit with the interrupt input signal (INTX\_EP\_F\*: active high). In addition, the value of this register is not reflected if the INTx message is asserted or deasserted by issuing a special request (prohibited operation). This register is only valid in endpoint mode.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0118h

**Initial Value:** 0000\_0000h

| 15 to 0      | —                                            | Reserved. These bits are read as 0b.                                                                         |

**(9) Message Receive Interrupt Status Register (PCI\_EP\_MSGRCVIS)**

This register is a status register that indicates the reception of message requests other than INTx and error-related messages. The value of this register is reflected in MSG\_INT. Only the message code is used to decide the message type, and the corresponding message is assumed to have been received while the validity of the routing and the validity of the Msg/MsgD selection are not verified.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0124h

**Initial Value:** 0000\_0000h

Table 35.5-16 PCI\_EP\_MSGRCVIS Register Contents

| Bit Position | Bit Name                              | Description                                                                                                                            |
|--------------|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 25     | —                                     | Reserved. These bits are read as 0b.                                                                                                   |
| 24           | Message Receive Interrupt             | Set in response to the reception of a message (regardless of the message type). It is cleared by writing 1b. Writing 0b has no effect. |
| 23 to 20     | —                                     | Reserved. These bits are read as 0b.                                                                                                   |
| 19           | PM_Active_State_Nak Receive Interrupt | Set in response to the reception of a PM_Active_State_Nak message.                                                                     |
| 18           | PM_PME Receive Interrupt              | EP is not supported.                                                                                                                   |
| 17           | PME_Turn_Off Receive Interrupt        | Set in response to the reception of a PME_Turn_Off message. Used in endpoint mode.                                                     |
| 16           | PME_TO_Ack Receive Interrupt          | EP is not supported.                                                                                                                   |
| 15 to 0      | —                                     | Reserved. These bits are read as 0b.                                                                                                   |

(10) Message Code Register (PCI\_EP\_MSGCODE)

This register stores the code and routing of the last received message.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0130h  
Initial Value: 0000\_0000h

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| Bit Position | Bit Name        | Description                                                                                                                              |
|--------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 16     | —               | Reserved. These bits are read as 0b.                                                                                                     |
| 15 to 8      | Message Code    | Stores the code of the last received message.                                                                                            |
| 7 to 5       | Routing         | Stores routing of the last received message.                                                                                             |
| 4 to 1       | —               | Reserved. These bits are read as 0b.                                                                                                     |
| 0            | Message Payload | Stores the presence or absence of the data payload of the last received message.<br>1b: MsgD (with payload)<br>0b: Msg (without payload) |

**Note:** When a Power Management message (PME\_TO\_Ack Message, PME\_Turn\_Off Message, PM\_PME Message, PM\_Active\_State\_Nak Message) is received, this register is not written.

(11) Message Data Register (PCI\_EP\_MSGDATA)

This register stores the data of the last received message.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0134h  
Initial Value: 0000\_0000h

Table 35.5-18 PCI\_EP\_MSGDATA Register Contents

| Bit Position | Bit Name     | Description                                                                                                                                                             |
|--------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | Message Data | Stores the first DW data of the last received message. Only updated when MsgD (with data) is received and retains the previous data when Msg (without data) is received |

**Note:** When a Power Management message (PME\_TO\_Ack Message, PME\_Turn\_Off Message, PM\_PME Message, PM\_Active\_State\_Nak Message) is received, this register is not written.

(12) Message Header 3rdDW Register (PCI\_EP\_MSGH3DW)

This register stores the header (3rd DW) of the last received message.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0138h  
Initial Value: 0000\_0000h

Table 35.5-19 PCI\_EP\_MSGH3DW Register Contents

| Bit Position | Bit Name              | Description                                              |
|--------------|-----------------------|----------------------------------------------------------|
| 31 to 0      | Message Header 3rd DW | Stores the header (3rd DW) of the last received message. |

**Note:** When a Power Management message (PME\_TO\_Ack Message, PME\_Turn\_Off Message, PM\_PME Message, PM\_Active\_State\_Nak Message) is received, this register is not written.

(13) Message Header 4thDW Register (PCI\_EP\_MSGH4DW)

This register stores the header (4th DW) of the last received message.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 013Ch  
Initial Value: 0000\_0000h

Table 35.5-20 PCI\_EP\_MSGH4DW Register Contents

| Bit Position | Bit Name              | Description                                              |
|--------------|-----------------------|----------------------------------------------------------|
| 31 to 0      | Message Header 4th DW | Stores the header (4th DW) of the last received message. |

**Note:** When a Power Management message (PME\_TO\_Ack Message, PME\_Turn\_Off Message, PM\_PME Message, PM\_Active\_State\_Nak Message) is received, this register is not written.

**(14) Interrupt Table Register (PCI\_EP\_INTTABLE)**

This register is an index of interrupt factors. The interrupt signal (active high) status of each category can be monitored in a list.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0140h

**Initial Value:** 00xx\_0000h

| Bit           | 31           | 30 | 29 | 28 | 27    | 26          | 25           | 24      | 23    | 22 | 21 | 20    | 19 | 18 | 17 | 16 |

Table 35.5-21 PCI\_EP\_INTTABLE Register Contents

| Bit Position | Bit Name     | Description                          |
|--------------|--------------|--------------------------------------|
| 31 to 24     | DMA_INT[7:0] | DMA_INT interrupt monitor register   |
| 23 to 15     | Debug        | Debug register                       |
| 14 to 12     | —            | Reserved. These bits are read as 0b. |
| 11           | Debug        | Debug register                       |
| 10           | AXI_ERR_INT  | Error interrupt monitor register     |
| 9            | PCIE_EVT_INT | Event interrupt monitor register     |
| 8            | MSG_INT      | Message interrupt monitor register   |
| 7 to 5       | —            | Reserved. These bits are read as 0b. |
| 4 to 0       | Debug        | Debug register                       |

**Note:** See the description of the terminal of the same name for details of the register.

**(15) PCIe Event Interrupt Enable 0 Register (PCI\_EP\_PEIE0)**

This register enables interrupts of each PCI Express event factors. This register enables writing to the PCIe Event Interrupt Status 1 Register (address: <PCI\_S0\_REG\_base> + 0204h).

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0200h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30                           | 29                           | 28              | 27 | 26 | 25    | 24    | 23    | 22 | 21    | 20 | 19 | 18 | 17 | 16 |

**Note:** Debug: Registers for use in debugging by Renesas. Note that a change from the initial value may lead to a malfunction.

**(16) PCIe Event Interrupt Status 0 Register (PCI\_EP\_PEIS0)**

This register is a status register to indicate interrupts of each PCI Express event factors. Set to 1b by the factor in the table. After checking the factor, write 1b to the corresponding bit to clear it.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0204h

**Initial Value:** 0000\_0000h

| Bit           | 31 | 30                        | 29                        | 28           | 27 | 26 | 25    | 24  | 23    | 22  | 21    | 20    | 19    | 18    | 17    | 16    |

**(17) PCIe Event Interrupt Enable 1 Register (PCI\_EP\_PEIE1)**

This register enables parity error and ECC error interrupts. When each bit is set to the valid setting, the value of each corresponding status bit of the PCIe event interrupt status 1 register (address: <PCI\_S0\_REG\_base> + 020Ch) becomes valid.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0208h

**Initial Value:** 0000\_0000h

Table 35.5-25 PCI\_EP\_PEIS1 Register Contents

| Bit Position | Bit Name                             | Description                                                                                                                                                                                                                                                                           |
|--------------|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 18     | —                                    | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                  |
| 17           | TXB_PARITY_ERR                       | TXB_PARITY_ERR interrupt. Notification of parity error interrupts in the Tx buffer mounted on the transaction layer.<br>It is cleared by writing 1b. Writing 0b has no effect.                                                                                                        |
| 16           | ERR_RPC_REPLAYFIFO_PERR              | ERR_RPC_REPLAYFIFO_PERR interrupt. Notification of parity error interrupts in the replay FIFO mounted on the data link layer.<br>It is cleared by writing 1b. Writing 0b has no effect.                                                                                               |
| 15 to 10     | —                                    | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                  |
| 9            | ERR_REPLAY_UPPER_CORRECTABLE_ERROR   | ERR_REPLAY_UPPER_CORRECTABLE_ERROR interrupt. Notification of ECC 1-bit error (correctable error) occurrence interrupts in the upper 64 bits of the data bus of the replay FIFO mounted on the data link layer.<br>It is cleared by writing 1b. Writing 0b has no effect.             |
| 8            | ERR_REPLAY_LOWER_CORRECTABLE_ERROR   | ERR_REPLAY_LOWER_CORRECTABLE_ERROR interrupt. Notification of ECC 1-bit error (correctable error) occurrence interrupts in the lower 64 bits of the data bus of the replay FIFO mounted on the data link layer.<br>It is cleared by writing 1b. Writing 0b has no effect.             |
| 7 to 2       | —                                    | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                  |
| 1            | ERR_REPLAY_UPPER_UNCORRECTABLE_ERROR | ERR_REPLAY_UPPER_UNCORRECTABLE_ERROR interrupt. Notification of ECC 2-bit or more error (uncorrectable error) occurrence interrupts in the upper 64 bits of the data bus of the replay FIFO mounted on the data link layer.<br>It is cleared by writing 1b. Writing 0b has no effect. |
| 0            | ERR_REPLAY_LOWER_UNCORRECTABLE_ERROR | ERR_REPLAY_LOWER_UNCORRECTABLE_ERROR interrupt. Notification of ECC 2-bit or more error (uncorrectable error) occurrence interrupts in the lower 64 bits of the data bus of the replay FIFO mounted on the data link layer.<br>It is cleared by writing 1b. Writing 0b has no effect. |

(19) AXI Master Error Interrupt Enable Register (PCI\_EP\_AMEIE)

This register enables the AXI master error interrupt.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0210h  
Initial Value: 0000\_0000h

|               |    |    |    |    |                          |    |    |    |    |    |    |    |                         |    |    |    |

(23) AXI Slave Error Interrupt Status 3 Register (PCI\_EP\_ASEIS3)

This register indicates the AXI ID at the time of the first AXI slave error.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0230h  
Initial Value: 0000\_0000h

Table 35.5-30 PCI\_EP\_ASEIS3 Register Contents

| Bit Position | Bit Name | Description                                                                                                                                                                                                                                                                               |
|--------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | ERR ID   | The ID at the time of the first error of the AXI Slave Error Interrupt Status 1 register (address: <PCI_S0_REG_base> + 0224h). Only the first error is saved. A new error ID can be saved when bits [11:8] and bits [1:0] of the AXI Slave Error Interrupt Status 1 register are cleared. |

**(24) PCIe Event Interrupt Enable 2 Register (PCI\_EP\_PEIE2)**

This register enables interrupts of the various PCI Express event factors. This register enables writing to the PCIe Event Interrupt Status 2 Register (address: <PCI\_S0\_REG\_base> + 0244h).

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0240h

**Initial Value:** 0000\_0000h

|--------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 17     | —                  | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                   |
| 16           | LTR_MECHANISM_EN   | Enables an interrupt for the CFG_LTR_MECHANISM change detection function.                                                                                                                                                                                                                                                                                              |
| 15 to 8      | D3_hot_err_EN      | Enables a D3_hot_err status detection interrupt at the time of the D3_EVENT_ACK/TURN_OFF_EVENT_ACK assertion if a transition to the D3hot state (CFG_POWERSTATE! = 0) is detected or a PME_TURN_OFF message is received in the pending state of the completion (ORT_TRANSACTION_PENDING = 1). Bits [15:10] are not used. The lower 2 bits correspond to each function. |
| 7 to 0       | CFG_POWER_STATE_EN | Enables a D_STATE_OUT_Fx (x = Function no.) pin change detection function interrupt. Bits [7:2] are not used. The lower 2 bits correspond to each function.                                                                                                                                                                                                            |

(25) PCIe Event Interrupt Status 2 Register (PCI\_EP\_PEIS2)

This register indicates the state of various PCI Express events.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0244h  
Initial Value: 0000\_0000h

Table 35.5-32 PCI\_EP\_PEIS2 Register Contents

| Bit Position | Bit Name        | Description                                                                                                                                                                                                                                                                                                                                                                  |
|--------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 24     | Debug           | Register for debugging                                                                                                                                                                                                                                                                                                                                                       |
| 23 to 17     | —               | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                         |
| 16           | LTR_MECHANISM   | This bit indicates the detection of changes to CFG_LTR_MECHANISM.                                                                                                                                                                                                                                                                                                            |
| 15 to 8      | D3_hot_err      | These bits indicate the D3_hot_err status detection at the time of the D3_EVENT_ACK/TURN_OFF_EVENT_ACK assertion if a transition to the D3hot state (CFG_POWERSTATE! = 0) is detected or the PME_TURN_OFF message is received in the pending state of the completion (ORT_TRANSACTION_PENDING = 1). Bits [15:10] are not used. The lower 2 bits correspond to each function. |
| 7 to 0       | CFG_POWER_STATE | This bit indicates the detection of changes to the D_STATE_OUT_Fx (x = Function no.) pin. Bits [7:2] are not used. The lower 2 bits correspond to each function.                                                                                                                                                                                                             |

(26) Permission Register (PCI\_EP\_PERM)

This register controls access to the CFGU register.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0300h  
Initial Value: 0000\_0000h

| 31 to 3      | —              | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                 |
| 2, 1         | Debug          | Debug register                                                                                                                                                                                                                                                                                                                                                       |
| 0            | Stealth Enable | Sets the stealth (invisible) function of the Bridge Register. The stealth function is to restrict access from the PCIe for security. Write access to this bit from the PCIe is invalid. The PCIe cannot access the all Bridge Registers when this function is enabled. Returns 0 when read.<br>0b: Disable the stealth function.<br>1b: Enable the stealth function. |

**(27) Reset Register (PCI\_EP\_RESET)**

This register resets the PCIe core. Supplied to the internal core by OR with the pin of the same name. For details of each pin, see the terminal information. The write value is saved when accessed from the AXI, but a low-level pulse is generated when the PCIe writes 0b. However, when the AXI has already written 0b, the signal remains at the low level. Writing 1b from the PCIe is ignored.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0310h

**Initial Value:** 0000\_00xxh

| Bit Position | Bit Name                      | Description                                                                                                                                                                                                                                                                                                            |
|--------------|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1            | STATE_VC0_NEGOTIATION_PENDING | Monitors flow control initialization operation.<br>When this bit is 1b, transactions should not be started by AXI. Confirm that this bit is 0b and DL_Down Status (bit [0]) is 0b.<br>0b: Indicates the completion of flow control initialization.<br>1b: Indicates that flow control initialization is not completed. |
| 0            | DL_down status                | Indicates whether the PCIe core is in the DL_Down or DL_Up state.<br>0b: DL_Up Status<br>1b: DL_Down Status                                                                                                                                                                                                            |

**(37) PCIe Core Control 2 Register (PCI\_EP\_PCCTRL2)**

This register controls the link speed/width change in the PCI Express core.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0410h

**Initial Value:** 003E\_0000h

**(38) PCIe Core Status 2 Register (PCI\_EP\_PCSTAT2)**

This register indicates the status of the link speed/width change in the PCI Express core.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0414h

**Initial Value:** xxxx\_xxxxh

| 20 to 16     | DMA_CH6_vec    | Specifies MSI interrupt vector transmitted by DMAC ch. 6.                                                      |
| 15, 14       | —              | Reserved. These bits are read as 0b.                                                                           |
| 13           | DMA_CH5_MSI_EN | DMA Ch5 MSI Enable<br>0b: MSI is not used (DMA interrupt notification by the DMA_INT pin).<br>1b: MSI is used. |
| 12 to 8      | DMA_CH5_vec    | Specifies MSI interrupt vector transmitted by DMAC ch. 5.                                                      |
| 7, 6         | —              | Reserved. These bits are read as 0b.                                                                           |
| 5            | DMA_CH4_MSI_EN | DMA Ch4 MSI Enable<br>0b: MSI is not used (DMA interrupt notification by the DMA_INT pin).<br>1b: MSI is used. |
| 4 to 0       | DMA_CH4_vec    | Specifies MSI interrupt vector transmitted by DMAC ch. 4.                                                      |

(42) DMAC Control Register (PCI\_EP\_DMACTRL)

This register sets the maximum size of read requests which can be issued to the PCIe Core as a DMAC function. Use the initial setting (128-byte). This setting is common to all DMA channels.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0800h  
Initial Value: 0000\_0000h

Table 35.5-51 PCI\_EP\_DMAINTS Register Contents (1/3)

| Bit Position | Bit Name        | Description                                                                                                                                                                                                                                                                                                                                                                     |
|--------------|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31           | CH7_ERR         | This bit is set when an error has occurred during DMA transfer. It is cleared by writing 1b. Writing 0b has no effect.                                                                                                                                                                                                                                                          |
| 30           | CH7_QUEUE_EMPTY | This bit is set when a list is removed from the descriptor queue (and is moved to become the descriptor list for execution) and this leads to the queue being empty. It is cleared by writing 1b. Writing 0b has no effect.                                                                                                                                                     |
| 29           | CH7_STOP        | This bit is set if DMAC is stopped while in progress. The DMAC is stopped in the following case:<br>RDMA_EN or QUE_EN was cleared to 0b by software during DMA transfer and processing for the request being issued was ended.<br>It is cleared by writing 1b. Writing 0b has no effect.                                                                                        |
| 28           | CH7_END         | This bit is set when transfer through the DMAC is completed normally. Successful completion indicates the following states. <ul style="list-style-type: none"> <li>Transfer of the amount of data indicated by DMA_SIZE is completed.</li> <li>End of the descriptor list for which the EI field is set to 1b</li> </ul> It is cleared by writing 1b. Writing 0b has no effect. |
| 27           | CH6_ERR         | This bit is set when an error has occurred during DMA transfer. It is cleared by writing 1b. Writing 0b has no effect.                                                                                                                                                                                                                                                          |
| 26           | CH6_QUEUE_EMPTY | This bit is set when a list is removed from the descriptor queue (and is moved to become the descriptor list for execution) and this leads to the queue being empty. It is cleared by writing 1b. Writing 0b has no effect.                                                                                                                                                     |
| 25           | CH6_STOP        | This bit is set when the DMAC is stopped while in progress. The DMAC is stopped in the following case:<br>RDMA_EN or QUE_EN was cleared to 0b by software during DMA transfer and processing for the request being issued was ended.<br>It is cleared by writing 1b. Writing 0b has no effect.                                                                                  |
| 24           | CH6_END         | This bit is set when transfer through the DMAC is completed normally. Successful completion indicates the following state. <ul style="list-style-type: none"> <li>Transfer of the amount of data indicated by DMA_SIZE is completed.</li> <li>End of the descriptor list for which the EI field is set to 1b</li> </ul> It is cleared by writing 1b. Writing 0b has no effect.  |
| 23           | CH5_ERR         | This bit is set when an error has occurred during DMA transfer. It is cleared by writing 1b. Writing 0b has no effect.                                                                                                                                                                                                                                                          |

**(45) DMA Channel Control Register m (PCI\_EP\_DMACHCTLm) (m = 0 to 7)**

This register sets the control method for each DMA channel. Set either register type or descriptor type.

- Setting QUE\_EN = 1b and QUE\_CLR = 1b is prohibited during register-type DMA transfer (TDMA\_EN = 1b).
- Setting RDMA\_EN = 1b is prohibited during descriptor-type DMA transfer (QUE\_EN = 1b).

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0900h (m = 0)  
 <PCI\_S0\_REG\_base> + 0980h (m = 1)  
 <PCI\_S0\_REG\_base> + 0A00h (m = 2)  
 <PCI\_S0\_REG\_base> + 0A80h (m = 3)  
 <PCI\_S0\_REG\_base> + 0B00h (m = 4)  
 <PCI\_S0\_REG\_base> + 0B80h (m = 5)  
 <PCI\_S0\_REG\_base> + 0C00h (m = 6)  
 <PCI\_S0\_REG\_base> + 0C80h (m = 7)

**Initial Value:** 0000\_0000h

| Bit Position | Bit Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 9      | —        | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 8            | QUE_CLR  | Queue Clear<br>The queue is cleared by writing 1b. The descriptor lists registered in the queue (those waiting for execution and the one currently being executed) are all cleared. Do not clear them during DMA execution. The value read is always 0b. Writing 1b is prohibited when QUE_EN is set.                                                                                                                                                                                                                                            |
| 7 to 2       | —        | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 1            | QUE_EN   | Queue Enable<br>Writing 1b to this bit enables the start of processing of descriptor lists registered in the descriptor queue and of DMA transfer (descriptor type). The bit is automatically cleared to 0b when DMA transfer is stopped (normally or abnormally). DMA transfer can also be stopped by writing 0b. However, it is only stopped after the completion of the request (from PCIe or AXI) currently being executed.                                                                                                                  |
| 0            | RDMA_EN  | Register-type DMA transfer Enable<br>Writing 1b to this bit starts DMA transfer (register type) and transfer specified in the RDMA_SIZE bits proceeds. It is automatically cleared to 0b when DMA has ended in response to the completion of DMA transfer or the detection of an error. DMA transfer can also be stopped by writing 0b. However, it is only stopped after the completion of the request (from PCIe or AXI) currently being executed.<br>1b: Register-type DMA transfer is started.<br>0b: Register-type DMA transfer is stopped. |

(46) QUE Entry (Lower) Register m (PCI\_EP\_QUEEmL) (m = 0 to 7)

This register sets the descriptor queue list. This setting value is registered as the DSA (DMA descriptor start address) of the queue list.

Access Size: 32 bits

Address(es): <PCI\_S0\_REG\_base> + 0908h (m = 0)  
<PCI\_S0\_REG\_base> + 0988h (m = 1)  
<PCI\_S0\_REG\_base> + 0A08h (m = 2)  
<PCI\_S0\_REG\_base> + 0A88h (m = 3)  
<PCI\_S0\_REG\_base> + 0B08h (m = 4)  
<PCI\_S0\_REG\_base> + 0B88h (m = 5)  
<PCI\_S0\_REG\_base> + 0C08h (m = 6)  
<PCI\_S0\_REG\_base> + 0C88h (m = 7)

Initial Value: 0000\_0000h

Table 35.5-53 PCI\_EP\_QUEEmL Register Contents

| Bit Position | Bit Name               | Description                                                                                                                                                                                      |
|--------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | QUE_ENTRY (DSA[31:00]) | Registers a descriptor list queue. This area becomes the DSA. Set the address where the first descriptor is stored. Since the setting is for 8-byte alignment, the lower 3 bits are fixed to 0b. |

**Note:** When these bits are read, any of the following will be read depending on the state of DMA transfer.

DMA transfer is proceeding: The descriptor list being executed

DMA transfer is stopped (when QUE\_EN has been automatically cleared): The last list to have been executed

DMA transfer is stopped (when QUE\_EN has been cleared by software): The list that has been stopped (during execution).

**(47) QUE Entry (Upper) Register m (PCI\_EP\_QUEE0U) (m = 0 to 7)**

This register sets the descriptor queue list. This setting value is registered as the EI (end interrupt), LS (list stop), and the label of the queue list. Register to the queue by writing to [31:24].

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 090Ch (m = 0)  
 <PCI\_S0\_REG\_base> + 098Ch (m = 1)  
 <PCI\_S0\_REG\_base> + 0A0Ch (m = 2)  
 <PCI\_S0\_REG\_base> + 0A8Ch (m = 3)  
 <PCI\_S0\_REG\_base> + 0B0Ch (m = 4)  
 <PCI\_S0\_REG\_base> + 0B8Ch (m = 5)  
 <PCI\_S0\_REG\_base> + 0C0Ch (m = 6)  
 <PCI\_S0\_REG\_base> + 0C8Ch (m = 7)

**Initial Value:** 0000\_0000h

Table 35.5-54 PCI\_EP\_QUEE0U Register Contents

| Bit Position | Bit Name          | Description                                                                                                                                                                         |
|--------------|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 26     | QUE_Registration  | Register to the queue by writing to [31:24]. The value read is always 0000_00b.                                                                                                     |
| 25           | QUE_ENTRY (EI)    | Specify whether to notify an interrupt (interrupt status CHx_END) when the processing of the descriptor list is completed.<br>1b: Notify the interrupt.<br>0b: Notify no interrupt. |
| 24           | QUE_ENTRY (LS)    | Specify whether to stop DMA transfer when the processing of the descriptor list is completed.<br>1b: Stop DMA transfer.<br>0b: Does not stop DMA transfer.                          |
| 23 to 16     | —                 | Reserved. These bits are read as 0b.                                                                                                                                                |
| 15 to 0      | QUE_ENTRY (LABEL) | This field represents the label of the list and there are no special rules for the setting procedures. The value can be set as desired.                                             |

**Note:** When these bits are read, any of the following will be read depending on the state of DMA transfer.  
 DMA transfer is proceeding: The descriptor list being executed  
 DMA transfer is stopped (when QUE\_EN has been automatically cleared): The last list to have been executed  
 DMA transfer is stopped (when QUE\_EN has been cleared by software): The list that has been stopped (during execution).

**(48) DMA Descriptor Control (Descriptor 00h) Register m (PCI\_EP\_DMADPCTLm) (m = 0 to 7)**

This register indicates the field value at offset 00h in the descriptor table. Only effective when the descriptor-type DMA transfer is selected (the value read has no meaning in the case of register-type transfer).

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0920h (m = 0)  
 <PCI\_S0\_REG\_base> + 09A0h (m = 1)  
 <PCI\_S0\_REG\_base> + 0A20h (m = 2)  
 <PCI\_S0\_REG\_base> + 0AA0h (m = 3)  
 <PCI\_S0\_REG\_base> + 0B20h (m = 4)  
 <PCI\_S0\_REG\_base> + 0BA0h (m = 5)  
 <PCI\_S0\_REG\_base> + 0C20h (m = 6)  
 <PCI\_S0\_REG\_base> + 0CA0h (m = 7)

**Initial Value:** 0000\_0000h

Table 35.5-55 PCI\_EP\_DMADPCTLm Register Contents

| Bit Position | Bit Name | Description                                                             |
|--------------|----------|-------------------------------------------------------------------------|
| 31 to 28     | DSCFM    | Indicates the DSCFM field value in the descriptor table being executed. |
| 27           | —        | Reserved. This bit is read as 0b.                                       |
| 26           | WBD      | Indicates the WBD field value in the descriptor table being executed.   |
| 25           | LE       | Indicates the LE field value in the descriptor table being executed.    |
| 24           | LV       | Indicates the LV field value in the descriptor table being executed.    |
| 23           | D        | Indicates the D field value in the descriptor table being executed.     |
| 22 to 16     | —        | Reserved. These bits are read as 0b.                                    |
| 15 to 0      | STS      | Indicates the STS field value in the descriptor table being executed.   |

(49) DMA Source Address (Descriptor 04h) Register m (PCI\_EP\_DMASRCAm) (m = 0 to 7)

This register sets the start address of the source for DMA transfer.

Access Size: 32 bits

Address(es): <PCI\_S0\_REG\_base> + 0924h (m = 0)  
<PCI\_S0\_REG\_base> + 09A4h (m = 1)  
<PCI\_S0\_REG\_base> + 0A24h (m = 2)  
<PCI\_S0\_REG\_base> + 0AA4h (m = 3)  
<PCI\_S0\_REG\_base> + 0B24h (m = 4)  
<PCI\_S0\_REG\_base> + 0BA4h (m = 5)  
<PCI\_S0\_REG\_base> + 0C24h (m = 6)  
<PCI\_S0\_REG\_base> + 0CA4h (m = 7)

Initial Value: 0000\_0000h

Table 35.5-56 PCI\_EP\_DMASRCAm Register Contents

| Bit Position | Bit Name   | Description                                                                                                                            |
|--------------|------------|----------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | DMA_S_ADDR | Sets the start address of the source for DMA transfer.<br>Since the setting is for 8-byte alignment, the lower 3 bits are fixed to 0b. |

**Note:** If the source address is for the PCIe space (DIR = 0b), the PCIe request address is set in combination with the DMA PCIe upper address (descriptor 10h). When descriptor-type DMA transfer is in process, writing to these bits is prohibited and the value read indicates the value of the SA field in the descriptor table being executed.

(50) DMA Destination Address (Descriptor 08h) Register m (PCI\_EP\_DMADSTAm) (m = 0 to 7)

This register sets the start address of the destination for DMA transfer.

Access Size: 32 bits

Address(es): <PCI\_S0\_REG\_base> + 0928h (m = 0)  
<PCI\_S0\_REG\_base> + 09A8h (m = 1)  
<PCI\_S0\_REG\_base> + 0A28h (m = 2)  
<PCI\_S0\_REG\_base> + 0AA8h (m = 3)  
<PCI\_S0\_REG\_base> + 0B28h (m = 4)  
<PCI\_S0\_REG\_base> + 0BA8h (m = 5)  
<PCI\_S0\_REG\_base> + 0C28h (m = 6)  
<PCI\_S0\_REG\_base> + 0CA8h (m = 7)

Initial Value: 0000\_0000h

Table 35.5-57 PCI\_EP\_DMADSTAm Register Contents

| Bit Position | Bit Name   | Description                                                                                                                                 |
|--------------|------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | DMA_D_ADDR | Sets the start address of the destination for DMA transfer.<br>Since the setting is for 8-byte alignment, the lower 3 bits are fixed to 0b. |

**Note:** If the destination address is for the PCIe space (DIR = 0b), the PCIe request address is set in combination with the DMA PCIe upper address (descriptor 10h). When descriptor-type DMA transfer is in process, writing to these bits is prohibited and the value read indicates the value of the DA field in the descriptor table being executed.

(51) DMA Size (Descriptor 0Ch) Register m (PCI\_EP\_DMASIZEm) (m = 0 to 7)

This register sets the number of bytes for DMA transfer. Reflects the field at offset 0Ch in the descriptor table.

Access Size: 32 bits

Address(es): <PCI\_S0\_REG\_base> + 092Ch (m = 0)  
<PCI\_S0\_REG\_base> + 09ACh (m = 1)  
<PCI\_S0\_REG\_base> + 0A2Ch (m = 2)  
<PCI\_S0\_REG\_base> + 0AACh (m = 3)  
<PCI\_S0\_REG\_base> + 0B2Ch (m = 4)  
<PCI\_S0\_REG\_base> + 0BACH (m = 5)  
<PCI\_S0\_REG\_base> + 0C2Ch (m = 6)  
<PCI\_S0\_REG\_base> + 0CACH (m = 7)

Initial Value: 0000\_0000h

Table 35.5-58 PCI\_EP\_DMASIZEm Register Contents

| Bit Position | Bit Name | Description                                                                                                                |
|--------------|----------|----------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | DMA_SIZE | Sets the number of bytes for DMA transfer.<br>Since the setting is for 8-byte alignment, the lower 3 bits are fixed to 0b. |

**Note:** When descriptor-type DMA transfer is in process, writing to these bits is prohibited and the value read indicates the value of the SIZE field in the descriptor table being executed. The number of bytes for transfer when the setting is 0000\_0000h is 1\_0000\_0000h.

(52) DMA PCIe Upper Address (Descriptor 10h) Register m (PCI\_EP\_DMAPCIEUAm) (m = 0 to 7)

This register sets the start address [63:32] for DMA transfer on the PCIe.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0930h (m = 0)  
<PCI\_S0\_REG\_base> + 09B0h (m = 1)  
<PCI\_S0\_REG\_base> + 0A30h (m = 2)  
<PCI\_S0\_REG\_base> + 0AB0h (m = 3)  
<PCI\_S0\_REG\_base> + 0B30h (m = 4)  
<PCI\_S0\_REG\_base> + 0BB0h (m = 5)  
<PCI\_S0\_REG\_base> + 0C30h (m = 6)  
<PCI\_S0\_REG\_base> + 0CB0h (m = 7)

Initial Value: 0000\_0000h

Table 35.5-59 PCI\_EP\_DMAPCIEUAm Register Contents

| Bit Position | Bit Name    | Description                                                  |
|--------------|-------------|--------------------------------------------------------------|
| 31 to 0      | DMA_PU_ADDR | Sets the start address [63:32] for DMA transfer on the PCIe. |

**Note:** When descriptor-type DMA transfer is in process, writing to these bits is prohibited and the value read indicates the value of the PUA field in the descriptor table being executed.

**(53) DMA Transaction Control (Descriptor 14h) Register m (PCI\_EP\_DMATCTLm) (m = 0 to 7)**

This register controls DMA transfer to the AXI and PCIe.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0934h (m = 0)  
 <PCI\_S0\_REG\_base> + 09B4h (m = 1)  
 <PCI\_S0\_REG\_base> + 0A34h (m = 2)  
 <PCI\_S0\_REG\_base> + 0AB4h (m = 3)  
 <PCI\_S0\_REG\_base> + 0B34h (m = 4)  
 <PCI\_S0\_REG\_base> + 0BB4h (m = 5)  
 <PCI\_S0\_REG\_base> + 0C34h (m = 6)  
 <PCI\_S0\_REG\_base> + 0CB4h (m = 7)

**Initial Value:** 0000\_0000h

| 7            | —            | Reserved. This bit is read as 0b.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 6 to 4       | DMA_FUNC     | Indicates the request function number issued to PCIe.                                                                                                                                                                                                                                                                                                                                                                                                                |
| 3 to 1       | —            | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                                                                                                                 |

Table 35.5-60 PCI\_EP\_DMATCTLm Register Contents (2/2)

| Bit Position | Bit Name | Description                                                             |
|--------------|----------|-------------------------------------------------------------------------|
| 0            | DMA_DIR  | Sets the direction of DMA transfer.<br>1b: AXI → PCIe<br>0b: PCIe → AXI |

**Note:** When descriptor-type DMA transfer is in process, writing to these bits is prohibited and the value read indicates the value of the CCH\_L, CCH\_D, TC, ATB, and DIR fields in the descriptor table being executed.

(54) DMA Descriptor Link Pointer (Descriptor 1Ch) Register m (PCI\_EP\_DMADPLPm) (m = 0 to 7)

This register indicates the field value at offset 1Ch in the descriptor table. Only effective when descriptor-type DMA transfer is selected (the value read has no meaning in the case of register-type transfer).

Access Size: 32 bits

Address(es): <PCI\_S0\_REG\_base> + 093Ch (m = 0)  
<PCI\_S0\_REG\_base> + 09BCh (m = 1)  
<PCI\_S0\_REG\_base> + 0A3Ch (m = 2)  
<PCI\_S0\_REG\_base> + 0ABCh (m = 3)  
<PCI\_S0\_REG\_base> + 0B3Ch (m = 4)  
<PCI\_S0\_REG\_base> + 0BBCh (m = 5)  
<PCI\_S0\_REG\_base> + 0C3Ch (m = 6)  
<PCI\_S0\_REG\_base> + 0CBCh (m = 7)

Initial Value: 0000\_0000h

Table 35.5-61 PCI\_EP\_DMADPLPm Register Contents

| Bit Position | Bit Name | Description                                                          |
|--------------|----------|----------------------------------------------------------------------|
| 31 to 0      | DMA_LP   | Indicates the LP field value in the descriptor table being executed. |

(55) DMA Rest Size Register m (PCI\_EP\_DMARESTSIZm) (m = 0 to 7)

This register indicates the number of bytes for which DMA transfer has not yet been completed.

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 0950h (m = 0)  
<PCI\_S0\_REG\_base> + 09D0h (m = 1)  
<PCI\_S0\_REG\_base> + 0A50h (m = 2)  
<PCI\_S0\_REG\_base> + 0AD0h (m = 3)  
<PCI\_S0\_REG\_base> + 0B50h (m = 4)  
<PCI\_S0\_REG\_base> + 0BD0h (m = 5)  
<PCI\_S0\_REG\_base> + 0C50h (m = 6)  
<PCI\_S0\_REG\_base> + 0CD0h (m = 7)

Initial Value: 0000\_0000h

Table 35.5-62 PCI\_EP\_DMARESTSIZm Register Contents

| Bit Position | Bit Name      | Description                                                                                                                             |
|--------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | DMA_REST_SIZE | Indicates the number of bytes for which DMA transfer has not yet been completed (common to register-type and descriptor-type transfer). |

(56) AXI Request Address Register m (PCI\_EP\_AREQAm) (m = 0 to 7)

This register indicates the address during AXI transfer that is in progress or for the most recently completed transfer.

Access Size: 32 bits

Address(es): <PCI\_S0\_REG\_base> + 0954h (m = 0)  
<PCI\_S0\_REG\_base> + 09D4h (m = 1)  
<PCI\_S0\_REG\_base> + 0A54h (m = 2)  
<PCI\_S0\_REG\_base> + 0AD4h (m = 3)  
<PCI\_S0\_REG\_base> + 0B54h (m = 4)  
<PCI\_S0\_REG\_base> + 0BD4h (m = 5)  
<PCI\_S0\_REG\_base> + 0C54h (m = 6)  
<PCI\_S0\_REG\_base> + 0CD4h (m = 7)

Initial Value: 0000\_0000h

Table 35.5-63 PCI\_EP\_AREQAm Register Contents

| Bit Position | Bit Name     | Description                                                                                                                                              |
|--------------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | AXI_REQ_ADDR | Indicates the address during AXI transfer that is in progress or for the most recently completed transfer (common to register type and descriptor type). |

(57) PCIe Request Address (Lower) Register m (PCI\_EP\_PREQAmL) (m = 0 to 7)

This register indicates the lower 32 bits of the address during PCIe transfer that is in progress or for the most recently completed transfer.

Access Size: 32 bits

Address(es): <PCI\_S0\_REG\_base> + 0958h (m = 0)  
<PCI\_S0\_REG\_base> + 09D8h (m = 1)  
<PCI\_S0\_REG\_base> + 0A58h (m = 2)  
<PCI\_S0\_REG\_base> + 0AD8h (m = 3)  
<PCI\_S0\_REG\_base> + 0B58h (m = 4)  
<PCI\_S0\_REG\_base> + 0BD8h (m = 5)  
<PCI\_S0\_REG\_base> + 0C58h (m = 6)  
<PCI\_S0\_REG\_base> + 0CD8h (m = 7)

Initial Value: 0000\_0000h

Table 35.5-64 PCI\_EP\_PREQAmL Register Contents

| Bit Position | Bit Name      | Description                                                                                                                                                                    |
|--------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | PCIE_REQ_ADDR | Indicates the lower 32 bits of the address during PCIe transfer that is in progress or for the most recently completed transfer (common to register type and descriptor type). |

(58) PCIe Request Address (Upper) Register m (PCI\_EP\_PREQAmU) (m = 0 to 7)

This register indicates the upper 32 bits of the address during PCIe transfer that is in progress or for the most recently completed transfer.

Access Size: 32 bits

Address(es): <PCI\_S0\_REG\_base> + 095Ch (m = 0)  
<PCI\_S0\_REG\_base> + 09DCh (m = 1)  
<PCI\_S0\_REG\_base> + 0A5Ch (m = 2)  
<PCI\_S0\_REG\_base> + 0ADCh (m = 3)  
<PCI\_S0\_REG\_base> + 0B5Ch (m = 4)  
<PCI\_S0\_REG\_base> + 0BDCh (m = 5)  
<PCI\_S0\_REG\_base> + 0C5Ch (m = 6)  
<PCI\_S0\_REG\_base> + 0CDCh (m = 7)

Initial Value: 0000\_0000h

Table 35.5-65 PCI\_EP\_PREQAmU Register Contents

| Bit Position | Bit Name      | Description                                                                                                                                                                    |
|--------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | PCIE_REQ_ADDR | Indicates the upper 32 bits of the address during PCIe transfer that is in progress or for the most recently completed transfer (common to register type and descriptor type). |

**(59) QUE Status Register m (PCI\_EP\_QUESTAm) (m = 0 to 7)**

This register indicates the state of the descriptor queue.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0960h (m = 0)  
 <PCI\_S0\_REG\_base> + 09E0h (m = 1)  
 <PCI\_S0\_REG\_base> + 0A60h (m = 2)  
 <PCI\_S0\_REG\_base> + 0AE0h (m = 3)  
 <PCI\_S0\_REG\_base> + 0B60h (m = 4)  
 <PCI\_S0\_REG\_base> + 0BE0h (m = 5)  
 <PCI\_S0\_REG\_base> + 0C60h (m = 6)  
 <PCI\_S0\_REG\_base> + 0CE0h (m = 7)

**Initial Value:** 0000\_0000h

Table 35.5-66 PCI\_EP\_QUESTAm Register Contents

| Bit Position | Bit Name | Description                                                                                                                                                                                                                                                                                                                          |
|--------------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 5      | —        | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                 |
| 4            | GO_LIST  | Indicates whether a descriptor list being executed is or is not present.<br>1b: Present<br>0b: Not present                                                                                                                                                                                                                           |
| 3 to 0       | LIST_NUM | Indicates the number of descriptor lists with which the queue for the given DMA channel has been loaded (any list currently being executed is not included). Attempts at making new entries in the queue while the value of this field is 8 (writing to the queue entry bits for the given channel) has no effect (will be ignored). |

**(60) DMAC Error Status Register m (PCI\_EP\_DMACESTAm) (m = 0 to 7)**

This register indicates the error status of the DMAC.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 0968h (m = 0)  
 <PCI\_S0\_REG\_base> + 09E8h (m = 1)  
 <PCI\_S0\_REG\_base> + 0A68h (m = 2)  
 <PCI\_S0\_REG\_base> + 0AE8h (m = 3)  
 <PCI\_S0\_REG\_base> + 0B68h (m = 4)  
 <PCI\_S0\_REG\_base> + 0BE8h (m = 5)  
 <PCI\_S0\_REG\_base> + 0C68h (m = 6)  
 <PCI\_S0\_REG\_base> + 0CE8h (m = 7)

**Initial Value:** 0000\_0000h

**(65) PCIe Window Mask m Register (Function #n) (PCI\_EP\_PWMASKm\_Fn) (m = 0 to 7, n = 0, 1)**

This register is for setting windows for address conversion in access from AXI to PCIe. The window is set as the area corresponding to the number of set bits from the address set in the PWBase register.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 1104h (m = 0, Funtion#0)  
 <PCI\_S0\_REG\_base> + 1114h (m = 1, Funtion#0)  
 <PCI\_S0\_REG\_base> + 1124h (m = 2, Funtion#0)  
 <PCI\_S0\_REG\_base> + 1134h (m = 3, Funtion#0)  
 <PCI\_S0\_REG\_base> + 1144h (m = 4, Funtion#0)  
 <PCI\_S0\_REG\_base> + 1154h (m = 5, Funtion#0)  
 <PCI\_S0\_REG\_base> + 1164h (m = 6, Funtion#0)  
 <PCI\_S0\_REG\_base> + 1174h (m = 7, Funtion#0)  
 <PCI\_S0\_REG\_base> + 1304h (m = 0, Funtion#1)  
 <PCI\_S0\_REG\_base> + 1314h (m = 1, Funtion#1)  
 <PCI\_S0\_REG\_base> + 1324h (m = 2, Funtion#1)  
 <PCI\_S0\_REG\_base> + 1334h (m = 3, Funtion#1)  
 <PCI\_S0\_REG\_base> + 1344h (m = 4, Funtion#1)  
 <PCI\_S0\_REG\_base> + 1354h (m = 5, Funtion#1)  
 <PCI\_S0\_REG\_base> + 1364h (m = 6, Funtion#1)  
 <PCI\_S0\_REG\_base> + 1374h (m = 7, Funtion#1)

**Initial Value:** 0000\_0FFFh

Table 35.5-77 PCI\_EP\_COM\_STA\_Fn Register Contents (1/2)

| Bit Position | Bit Name                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31           | Detected Parity Error                 | Set to 1b when a poisoned TLP is received regardless of the setting of the Parity Error Response bit. It is cleared by writing 1b during PCIe access. Writing 0b has no effect.                                                                                                                                                                                                                                                |
| 30           | Signaled System Error                 | Set to 1b when this unit has transmitted an ERR_FATAL or ERR_NONFATAL message while the SERR Enable bit is 1b. It is cleared by writing 1b during PCIe access. Writing 0b has no effect.                                                                                                                                                                                                                                       |
| 29           | Received Master Abort                 | Set to 1b when a received Completion Status field indicates the completion of an unsupported request. It is cleared by writing 1b during PCIe access. Writing 0b has no effect.                                                                                                                                                                                                                                                |
| 28           | Received Target Abort                 | Set to 1b when a received Completion Status field indicates the completer abortion state. It is cleared by writing 1b during PCIe access. Writing 0b has no effect.                                                                                                                                                                                                                                                            |
| 27           | Signaled Target Abort                 | Set to 1b when the Completion Status field indicated the completer abortion state at the time of transmission for completion. It is cleared by writing 1b during PCIe access. Writing 0b has no effect.                                                                                                                                                                                                                        |
| 26, 25       | DEVSEL Timing                         | Reserved. Does not apply to PCI Express. (Fixed to 00b.)                                                                                                                                                                                                                                                                                                                                                                       |
| 24           | Master Data Parity Error              | Set to 1b when the setting of the Parity Error Response bit becomes 1b and either of the following two conditions is satisfied.<br>– The requester (BME) having received a poisoned completion TLP<br>– The Requester (BME) having transmitted a poisoned write request TLP<br><br>This bit is not set to 1b if the Parity Error Response bit is 0b. It is cleared by writing 1b during PCIe access. Writing 0b has no effect. |
| 23           | Fast Back-to-Back Transaction Capable | Reserved. Does not apply to PCI Express (fixed to 0b).                                                                                                                                                                                                                                                                                                                                                                         |

(8) Base Address Register 3 (Function #n) (PCI\_EP\_BAR3\_Fn) (n = 0, 1)

This register forms a 64-bit memory space in combination with Base Address Register 2 (BAR2).

Access Size: 32 bits  
Address(es): <PCI\_S0\_REG\_base> + 601Ch (Function #0)  
<PCI\_S0\_REG\_base> + 701Ch (Function #1)  
Initial Value: 0000\_0000h

Table 35.5-89 PCI\_EP\_BAR3\_Fn Register Contents

| Bit Position | Bit Name                | Description                                                                                                                                                                                                                                                                           |
|--------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0      | Base Address Register 3 | Indicates the base address. Some lower bits of this field are implemented as read-only bits that are fixed to 0b to suit the required size of the address block. Read-only bits of this unit can be set in Base Address Register Mask01 (Upper) (address: <PCI_S0_REG_base> + 60ACh). |

Table 35.5-107 PCI\_EP\_DEVCS\_Fn Register Contents (1/2)

| Bit Position | Bit Name                           | Description                                                                                                                                                                  |
|--------------|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 23     | —                                  | Reserved. These bits are read as 0b.                                                                                                                                         |
| 22           | Emergency Power Reduction Detected | Not supported. Fixed to 0b.                                                                                                                                                  |
| 21           | Transaction Pending                | Indicates that the transaction is pending because no completion has been received for the transmitted non-posted request. 1b indicates pending.                              |
| 20           | AUX Power Detected                 | Indicates that auxiliary power was detected (AUX is not supported).                                                                                                          |
| 19           | Unsupported Request Detected       | Indicates that an unsupported request error was detected. 1b indicates that an error was detected. It is cleared by writing 1b during PCIe access, writing 0b has no effect. |
| 18           | Fatal Error Detected               | Indicates that a fatal error was detected. 1b indicates that an error was detected. It is cleared by writing 1b. Writing 0b has no effect.                                   |
| 17           | Non-Fatal Error Detected           | Indicates that a non-fatal error was detected. 1b indicates that an error was detected. It is cleared by writing 1b during PCIe access, writing 0b has no effect.            |
| 16           | Correctable Error Detected         | Indicates that a correctable error was detected. 1b indicates that an error was detected. It is cleared by writing 1b during PCIe access, writing 0b has no effect.          |
| 15           | Initiate Function Level Reset      | A write of 1b initiates a function level reset to the Function. The value read by software from this bit is always 0b.                                                       |

**(20) Link Control/Status (Function #n) (PCI\_EP\_LINKCS\_Fn) (n = 0, 1)**

This register controls the link and indicates the link status.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 6070h (Function #0)  
<PCI\_S0\_REG\_base> + 7070h (Function #1)

**Initial Value:** 1000\_0000h

|--------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 26     | —            | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                                             |
| 25 to 16     | Base Size 03 | Sets the size of TLP (DW Size) accepted by Address Space xx set by Base Address Register and Base Address Mask Register. When a TLP with a packet length greater than the size set in these bits is received, even if it is smaller than the max payload size, a completer abort error (CA) is detected. Note that the initial value is 00_0000_0000b and this function is invalid in this case. |
| 15 to 10     | —            | Reserved. These bits are read as 0b.                                                                                                                                                                                                                                                                                                                                                             |
| 9 to 0       | Base Size 02 | Sets the size of TLP (DW Size) accepted by Address Space xx set by Base Address Register and Base Address Mask Register. When a TLP with a packet length greater than the size set in these bits is received, even if it is smaller than the max payload size, a completer abort error (CA) is detected. Note that the initial value is 00_0000_0000b and this function is invalid in this case. |

Table 35.5-141 PCI\_EP\_TSUPPORT00\_01\_02\_Fn Register Contents

| Bit Position | Bit Name               | Description                                                                                                                      |
|--------------|------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| 31 to 24     | Debug                  | This register is for use in debugging by Renesas. Note that a change from the initial value may lead to a malfunction.           |
| 23 to 16     | Type Supported 02      | Sets the transaction type which can be supported by Space02 (CFG_SPACE02_BASE). The meaning of each bit is indicated as follows. |
| 15 to 8      | Type Supported 01      | Sets the transaction type which can be supported by Space01 (CFG_SPACE01_BASE). The meaning of each bit is indicated as follows. |
| 7 to 0       | Type Supported 00[7:0] | Sets the transaction type which can be supported by Space00 (CFG_SPACE00_BASE). The meaning of each bit is indicated as follows. |

**Note:** Bit 0: 32-bit memory read  
 Bit 1: 64-bit memory read  
 Bit 2: 32-bit memory read lock  
 Bit 3: 64-bit memory read lock  
 Bit 4: 32-bit memory write  
 Bit 5: 64-bit memory write  
 Bit 6: IO read  
 Bit 7: IO write

Table 35.5-142 Valid Reset Signal

| Reset Signal | Debug | Type Supported 02 | Type Supported 01 | Type Supported 00 |
|--------------|-------|-------------------|-------------------|-------------------|

| Bit Position | Bit Name              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 16     | Extended Message Data | Not supported. Fixed to 0000h.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 15 to 0      | Message Data          | Set data to be set in MSI messages. When the Multiple Message Enable field is 011b (8), the function (AXI) can change the lower 3 bits of message data and notify the system of 8 vectors as message data. Similarly, when the value is 010b (4), the function (AXI) can change the lower 2 bits to notify 4 vectors. When the value is 001b (2), the function (AXI) can change the lower 1 bit to notify 2 vectors. When it is 000b (1), the function (AXI) can notify only 1 vector.<br><br><i>Note:</i> The invalid upper bits of the function specification data (for example, in the case of above Multiple Message Enable setting 4, the upper bits except the lower 2 bits changed by Function) should specify 0b. |

Table 35.5-150 Valid Reset Signal

| Reset Signal | Message Data |
|--------------|--------------|
| RST_LOAD_B   |              |

**(44) Uncorrectable Error Mask Register (Function #n) (PCI\_EP\_UNCEMASK\_Fn) (n = 0, 1)**

This register masks the uncorrectable error status.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 6108h (Function #0)  
<PCI\_S0\_REG\_base> + 7108h (Function #1)

**Initial Value:** 0000\_0000h

**(45) Uncorrectable Error Severity Register (Function #n) (PCI\_EP\_UNCESVY\_Fn) (n = 0, 1)**

This register sets the uncorrectable error severity.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 610Ch (Function #0)  
<PCI\_S0\_REG\_base> + 710Ch (Function #1)

**Initial Value:** 0046\_2030h

Table 35.5-170 PCI\_EP\_HLOG3\_Fn Register Contents

| Bit Position | Bit Name                              | Description                                                                          |
|--------------|---------------------------------------|--------------------------------------------------------------------------------------|
| 31 to 0      | Header of TLP associated with error 3 | Indicates the 4th DW of the header where the first uncorrectable error was detected. |

### (53) Device Serial Number Extended Capability Register (Function #n) (PCI\_EP\_DEVSNEXTC\_Fn) (n = 0, 1)

This register specifies the device serial number extended capability.

**Access Size:** 32 bits

**Address(es):** <PCI\_S0\_REG\_base> + 6150h (Function #0)  
<PCI\_S0\_REG\_base> + 7150h (Function #1)

**Initial Value:** 0001\_0003h

## 35.6 PHY Register Descriptions

For more information, contact a Renesas Electronics sales representative.

## 35.7 Functional Description

### 35.7.1 PCIe Core Functions

The functional description of the unit is given below.

This unit is configured based on the Base Spec 4.0. For the detailed specification, refer to the Base Spec 4.0. This section mainly describes the parts specific to Renesas Electronics.

### 35.7.2 Issuing of PCIe Requests and Register Access (by AXI)

The following gives functional description on access to the PCI Express core by the AXI bus.

#### 35.7.2.1 PCIe Requests which can be Issued (Supported Commands for TX)

##### Requests to be issued via pcie windows

MRd: Memory Read Request

MWr: Memory Write Request

##### Requests to be issued by the registers

MRd: Zero-Length Memory Read Request

CfgRd0: Configuration Read Type 0

CfgWr0: Configuration Write Type 0

CfgRd1: Configuration Read Type 1

CfgWr1: Configuration Write Type 1

Msg: Message Request

MsgD: Message Request with data payload

##### Unsupported requests (issuance prohibited)

IORd: I/O Read Request

IOWr: I/O Write Request

MRdLk: Memory Read Request-Locked

CplDLk: Completion for Locked Memory Read

#### CAUTION

If non-posted request with data (CfgWr0/CfgWr1/IOWr) which should not be transmitted is issued inadvertently in EPS mode, an MRd (non-posted request without data) which can be normally transmitted in EP mode may not also be transmitted after that.

### 35.7.2.2 Register Access

- 1) Internal register read/write
- 2) Configuration register read/write

The following restrictions apply to access to the configuration registers.

- Byte-lane transfer is only acceptable if the transfer consists of consecutive valid bytes.
- If the valid bytes are not consecutive, only values which are no greater than 32 bits (1 dword) and do not span the dword alignment are acceptable.

*Example)* A value which can represent a dword TLP for PCIe

### 35.7.2.3 Issuing Memory Requests

Access from the AXI side is converted into a PCIe request and then issued. Up to eight windows can be allocated. Note that only incremental bursts and fixed bursts (of 1 beat) are acceptable. Wrapping bursts and fixed bursts (of 2 or more beats) are prohibited. If these prohibited bursts are received, the unit operates as follows.

- Although the response will in general be “OKAY” (except in cases that involved a protocol error of the AXI), this is beyond the scope of guaranteed operation.
- Unexpected requests may be issued to the PCIe bus.
- Unexpected registers may be modified.

To maintain the order between memory writing and memory reading, only issue next transactions after the reception of responses to writing. Buffering is not available in the issuing of memory write requests. (Refer to the description of AWCACHE\* of Mode Set 0 Register (offset: 314h).)

#### (1) Memory Write Transaction from the AXI

A write transaction from the AXI via a window is converted into a MWr command and then issued.

- Number of write transactions which can be accepted at a time: 1
- Write data are held in an internal buffer.
- The order between memory write transactions is preserved (with the exception of transactions for messages and configuration).
- The order of memory write and other transactions is not preserved (a preceding memory read may be overtaken).
- To preserve the order between memory writing and memory reading or of Msg and MsgD, make sure that a next transaction is only issued after a response is returned. Buffering is not available in the issuing of memory write requests.
- Writing does not proceed if the PCI power state is not D0.
- Transactions where all bits of WSTRB are 0 during a burst return an “OKAY” response, but the written data are not reflected.
- Memory requests are not issued after an acknowledgement for PME\_Turn\_Off Message reception/Non-D0 State transition request reception has been asserted (Precautions: Only for Endpoint mode).

## (2) Memory Read Transaction from the AXI

A read transaction from the AXI via a window is converted into an MRd command and then issued.

- Number of read transactions which can be accepted at a time: 1 to 8
- Read data are held in an internal buffer to preserve the order of transactions with the same ID.
- To preserve the order of memory read transactions from a given master ID, the system can also wait until the indicator of completion of a preceding read transaction is returned. The method of waiting is selectable as either of the above by the setting of an internal register as listed in the table below.

| PCIe Request Order* <sup>1</sup> | Method of Waiting                                     | Performance | Severity of Order |
|----------------------------------|-------------------------------------------------------|-------------|-------------------|
| 0 (initial value)                | Data read are held in an internal buffer.             | ✓           | —                 |
| 1                                | Have the system wait for a read request to be issued. | —           | ✓                 |

Note 1. The order can be set by using the PCIe Request Order bit (bit [0]) of Mode Set 1 Register (offset: 318h).

- The order of memory read transactions from a different master ID is not preserved.
- The order of memory read and other transactions is not preserved.
- To preserve the order between memory reading and memory writing, make sure that a next transaction is only issued after a response is returned. Buffering is not available in the issuing of memory write requests.
- MRdLk requests are not supported and therefore cannot be issued.
- Reading does not proceed if the PCI power state is not D0.
- Memory requests are not issued after an acknowledgement for PME\_Turn\_Off Message reception/Non-D0 State transition request reception has been asserted (Precautions: Only for Endpoint mode).

### 35.7.2.4 Issuing Special Requests

The following requests can be issued by controlling the internal registers.

- Configuration Read
- Configuration Write
- Zero-Length Memory Read Request
- Message Request
- Message Request with data payload

The internal registers are only writable from the AXI side. Attempted writing from the PCIe side is ignored and the write operation returns an “OKAY” response, but the written data are not reflected.

The figure below shows the flow of issuing requests by the registers.

### (1) Issuing Message Requests

A message request is automatically issued by setting the Request Issue bit (bit [0]) of the Request Issue Register after access to an internal register through the AXI slave interface and setting a destination in Request Address Register 1.

#### (a) Flow of Issuing Message Requests

An example of the flow of issuing message requests is described below.

1. Set a destination in Request Address Register 1.

|                            |                              |
|----------------------------|------------------------------|
| Bits [31:27]: Reserved     | Fixed to 0_0000b.            |
| Bits [26:24]: Routing Type | Specify the message routing. |
| Bits [23:8]: Reserved      | Fixed to 0000h.              |
| Bits [7:0]: Message Code   | Specify the message code.    |

2. Set the 3rd header in Request Data Register 1 as required.
3. Set the 4th header in Request Data Register 2 as required.
4. For MsgD, set write data in Request Data Register 3 (not required in the case of Msg).
5. Message requests are automatically issued by setting the Request Issue bit (bit [0]) of the Request Issue Register to 1b (the TR type bits (bits [11:8]) of the Request Issue Register are used to set Msg/MsgD).
6. Read the Request Issue Register and wait (polling) or wait for an interrupt of Request Done (bit [28]) of PCIe Event Interrupt Status 0 Register until the Request Issue bit (bit [0]) is set to 0b, wait for the request to end.

#### (b) Notes when Issuing Message Requests

Points to note when issuing message requests are described below.

- INTx and error type messages are automatically issued. They do not require issuing as message requests by the user (prohibited).
- Set message headers appropriately.
- A value to be set in a message header must be 0 except when sending a vendor defined message.

## (2) Issuing Zero-Length Read Requests

A zero-length read request is automatically issued by setting a destination in Request Address Register 1 after access to an internal register through the AXI slave interface and setting the Request Issue bit (bit [0]) of the Request Issue Register.

### (a) Flow of Issuing Zero-Length Read Requests

An example of the flow of issuing zero-length read requests is described below.

1. Set a destination in Request Address Register 1.  
Bits [31:2]: Address      Set the address.  
Bits [1:0]:    Reserved    Fixed to 00b.
2. Set a destination in Request Address Register 1.  
Bits [64:32]: Address      Set the address.
3. Set Byte Enable (0000b) in Request Byte Enable Register.
4. Zero-length read requests are automatically issued by setting the Request Issue bit (bit[ 0]) of the Request Issue Register to 1b (the TR type bits (bits [11:8]) of the Request Issue Register are used to set zero-length read).
5. Read the Request Issue Register and wait (polling) or wait for an interrupt of Request Done (bit [28]) of PCIe Event Interrupt Status 0 Register until the Request Issue bit (bit [0]) is set to 0b, wait for the request to end.

### 35.7.3 Initiation of AXI Transactions and Register Access (by PCIe)

The following gives functional description on access to the AXI bus by the PCI Express core.

#### 35.7.3.1 PCIe Requests which can be Received (Supported Commands for RX)

|         |                                   |
|---------|-----------------------------------|
| MRd:    | Memory Read Request               |
| MWr:    | Memory Write Request              |
| CfgRd0: | Configuration Read Type 0         |
| CfgWr0: | Configuration Write Type 0        |
| Msg:    | Message Request                   |
| MsgD:   | Message Request with data payload |
| Cpl:    | Completion                        |
| CplD:   | Completion with Data              |

The following requests are not supported.

|         |                                                |
|---------|------------------------------------------------|
| MRdLk:  | Memory Read Request-Locked                     |
| IORd:   | I/O Read Request                               |
| IOWr:   | I/O Write Request                              |
| CplLK:  | Completion for Locked Memory Read without Data |
| CplDLk: | Completion for Locked Memory Read              |
| CfgRd1: | Configuration Read Type 1                      |
| CfgWr1: | Configuration Write Type 1                     |

AtomicOP is not supported.

### 35.7.3.2 Initiation of AXI Transactions

Access from the PCIe side is converted into an AXI transaction and then issued. Up to eight windows can be allocated.

To avoid a read-after-write (RAW) hazard, only issue a next memory write request following reception of the completion TLP for the previous one.

Table 35.7-1 AXI Transaction from PCIe Request

| PCIe Request | AXI Burst Type      | AXI Bus Size | Division |
|--------------|---------------------|--------------|----------|
| MWrr/MRrd    | Incremental         | 64           | Yes      |
|              |                     | 32           | No       |
| IOWrr/IORrd  | Unsupported request |              |          |
| MRrdLk       | Unsupported request |              |          |

#### (1) Memory Write Transaction from the PCIe

- Allowable number of write requests to be issued: Variable (the value is set by the AXI Max Issue Write bits (bits [15:12]) of Mode Set 1 Register).
- Write data are not held in an internal buffer (buffering within the PCIe core).
- The order between memory write transactions is preserved.
- The order of memory writing and memory reading is not preserved.
- To preserve the order between memory writing and memory reading, make sure that a next request is only issued after a completion TLP is returned.
- AWCACHE and AWPROT can be set by using Mode Set 0 Register.
- In cases of contention between DMA transfer (from PCIe to AXI) and memory write transaction, requests are accepted in turn in round-robin fashion.

#### (2) Memory Read Transaction from the PCIe

- Allowable number of read requests to be issued: Variable (the value is set by the AXI Max Issue Read bits (bits [11:8]) of Mode Set 1 Register).
- Since the PCI specification requires dword-aligned memory addresses in transfer, invalid byte lanes may be read. If an AXI slave as a read destination has a register or FIFO buffer which has been cleared by being read, the transaction may be non-compliant.
- Data read are held in an internal buffer.
- The order between memory read operations is preserved.
- A preceding memory write is not overtaken.  
Data read are held in an internal buffer until a preceding memory write is completed.  
When a zero-length read request is received, an “OKAY” response is returned, but the written data are not reflected and a completion TLP is transmitted after waiting for the completion of the preceding memory write.  
Data read are held in an internal buffer until a preceding memory write is completed.
- ARCACHE can be set by using Mode Set 0 Register.
- In cases of contention between DMA transfer (from AXI to PCIe) and memory read transaction, requests are accepted in turn in round-robin fashion.

### 35.7.3.3 Narrow Transfer

Narrow transfer to be initiated by the AXI transfer only supports the following AXI transactions.

- MAXBURST = INCR
- MAXSIZE = 0h to 2h (8 bits / 16 bits / 32 bits)
- MAXLEN = 0h (1 beat)

The following restrictions apply to TLPs from the PCIe module in narrow transfer.

- The length is 1 dword.
- The First Byte Enable bit only supports the following.
  - MAXSIZE = 0h (8 bits): 1000b / 0100b / 0010b / 0001b
  - MAXSIZE = 1h (16 bits): 1100b / 0011b
  - MAXSIZE = 2h (32 bits): 1111b

### 35.7.4 DMAC Functions

This section explains functions of the DMAC within the unit. Control by registers and by descriptors are both supported as methods of DMA control. The method of control is independently selected per channel.

#### 35.7.4.1 Register-Type Transfer

DMA transfer from AXI to PCIe or vice versa is handled by software making register settings. The table below lists the DMAC registers for execution of register-type DMA transfer.

Table 35.7-2 Registers Related to Register-Type DMA Transfer

|                       |                                        |
|-----------------------|----------------------------------------|
| Common Control        |                                        |
| 800h                  | DMAC Control Register                  |
| 808h                  | DMAC Interrupt Enable Register         |
| 80Ch                  | DMAC Interrupt Status Register         |
| Channel Control       |                                        |
| 900h + channel offset | DMA Channel Control Register m         |
| DMA Setting           |                                        |
| 924h + channel offset | DMA Source Address Register m          |
| 928h + channel offset | DMA Destination Address Register m     |
| 92Ch + channel offset | DMA Size Register m                    |
| 930h + channel offset | DMA PCIe Upper Address Register m      |
| 934h + channel offset | DMA Transaction Control Register m     |
| DMA Status            |                                        |
| 950h + channel offset | DMA Rest Size Register m               |
| 954h + channel offset | AXI Request Address Register m         |
| 958h + channel offset | PCIe Request Address(Lower) Register m |
| 95Ch + channel offset | PCIe Request Address(Upper) Register m |
| 968h + channel offset | DMAC Error Status Register m           |

## (1) Flow of Operations

The following describes the procedures for settings to activate and stop the DMAC in the case of register-type transfer.

### (a) Activation and Normal Operation

Before activating the DMAC, set the PCIe and AXI windows. After that, set the registers of the DMAC to start the DMAC.

**(b) Stopping DMA Transfer**

The following describes the procedure for settings to stop DMA transfer under software control.

- DMA transfer can be stopped by writing 0b to the RDMA\_EN (register type DMA control enable) bit (bit [0]) of the DMAC channel control register (offset: 900h + channel offset).
- Following the detection of RDMA\_EN being 0b, the unit waits for the completion of any request which has already been issued before asserting the interrupt signal (DMA\_INT).
- After waiting for the assertion of DMA\_INT, poll the CHx\_STOP bit of the DMA Interrupt Status Register (offset: 80Ch) to check that its value is 1b.
- This indicates that DMA transfer has been stopped. If the CHx\_STOP bit is 0b, check the CHx\_END bit for the given channel in the same register.
- If a last request is still being executed when RDMA\_EN is set to 0b, the CHx\_END bit indicates the completion of DMA transfer as in normal operation.
- The address to which transfer was most recently completed before it was stopped and the remaining number of bytes for transfer can be checked by reading the DMA Status registers (offset: 950h + channel offset to 95Ch + channel offset) for the given channel.

(c) Error Processing

If an error is detected in the AXI bus or a PCIe link while DMA transfer is in progress, the DMA\_INT interrupt signal is asserted.

Check the channel where the error was found (CHx\_ERR = 1b) by using the DMAC Interrupt Status Register (offset: 80Ch) and also the type of error by using the DMAC Error Status Register (offset: 968h + channel offset) as required.

Clear the CHx\_ERR bit that is currently set in the DMAC interrupt status register (offset: 80Ch) by writing 0b to it and check the address to which transfer was most recently completed before it was stopped and the remaining number of bytes for transfer by reading the DMA Status registers (offset: 950h + channel offset to 95Ch + channel offset) for the given channel.

35.7.4.2 Descriptor-Type Transfer

Consecutive DMA transfer is achieved by sequentially reading descriptors which indicate parameters of DMA transfer. Descriptors are allocated to the AXI memory space and the descriptor lists indicate the addresses where the descriptors start. This DMAC has a queue for storing multiple descriptor lists and these descriptor lists are written by software. The first list loaded in the queue is executed after being moved to become the descriptor list for execution following the detection of the condition for starting DMA transfer (the DMAC retains up to nine lists, including the one currently being executed).

Descriptors can have a chained configuration; execution of a descriptor list ends on detection of the last descriptor, and if the queue has a next list, execution of the next descriptor follows.

Figure 35.7-1 Descriptor Chain

The table below lists the DMAC registers for execution of descriptor-type DMA transfer.

Table 35.7-3 Registers Related to Descriptor-Type DMA Transfer

| Common Control        |                                                         |
|-----------------------|---------------------------------------------------------|
| 800h                  | DMAC Control Register                                   |
| 808h                  | DMAC Interrupt Enable Register                          |
| 80Ch                  | DMAC Interrupt Status Register                          |
| Channel Control       |                                                         |
| 900h + channel offset | DMA Channel Control Register                            |
| 908h + channel offset | QUE Entry (Lower) Register                              |
| 90Ch + channel offset | QUE Entry (Upper) Register                              |
| DMA Setting           |                                                         |
| 920h + channel offset | DMA Descriptor Control (Descriptor 00h) Register m      |
| 924h + channel offset | DMA Source Address (Descriptor 04h) Register m          |
| 928h + channel offset | DMA Destination Address (Descriptor 08h) Register m     |
| 92Ch + channel offset | DMA Size (Descriptor 0Ch) Register m                    |
| 930h + channel offset | DMA PCIe Upper Address (Descriptor 10h) Register m      |
| 934h + channel offset | DMA Transaction Control (Descriptor 14h) Register m     |
| 93Ch + channel offset | DMA Descriptor Link Pointer (Descriptor 1Ch) Register m |
| DMA Status            |                                                         |
| 950h + channel offset | DMA Rest Size Register m                                |
| 954h + channel offset | AXI Request Address Register m                          |
| 958h + channel offset | PCIe Request Address(Lower) Register m                  |
| 95Ch + channel offset | PCIe Request Address(Upper) Register m                  |
| 960h + channel offset | QUE Status Register m                                   |
| 968h + channel offset | DMAC Error Status Register m                            |

### (1) Descriptor List Queues

The DMAC has queues for storing descriptor lists for each of the channels. The number of FIFO queue stages is eight, so it can hold up to eight descriptor list entries (not including the one currently being executed).

Software places descriptor list entries in the queue. The descriptor lists to be entered are set by the combination of the QUE\_ENTRY (upper) register and the QUE\_ENTRY (lower) register in 64-bit (or 8-byte) units.

Since the target registers are also accessible in 8-bit units, making the settings in byte units through multiple accesses is also possible. A descriptor list entry is placed in the queue at the time when the QUE\_ENTRY (upper) bits [31:24] are written. When making the settings and entering lists in the queue, take care with the order of register access (values written to the QUE\_ENTRY (upper) bits [31:26] will not affect the register values and settings because they are read-only bits).

When the DMAC detects the presence of a list which has been entered in the queue, the first list entry is moved to become the pointer to the next descriptor for execution and DMA transfer starts.

## (2) Descriptor List Format

The table below is the format of a descriptor list.

Table 35.7-4 Descriptor List Format

| Offset | Byte 3   |  |    |    | Byte 2   |  |  |  | Byte 1 |  |  |  | Byte 0 |  |  |  |
|--------|----------|--|----|----|----------|--|--|--|--------|--|--|--|--------|--|--|--|
|        |          |  |    |    |          |  |  |  |        |  |  |  |        |  |  |  |
| 00h    | DSA      |  |    |    |          |  |  |  |        |  |  |  |        |  |  |  |
| 04h    | Reserved |  | EI | LS | Reserved |  |  |  | LABEL  |  |  |  |        |  |  |  |

| Field Name  | Description                                                                                                                                                                                                                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DSA[31:0]   | Descriptor start address for DMA.<br>This field indicates the address where the first descriptor to be executed is stored.<br>Since the setting is for 8-byte alignment and allocation of a single descriptor (00h to 1Ch) to straddle a 4-K boundary is prohibited, the 5 lower-order bits [4:0] are fixed to 0b. |
| EI          | End Interrupt bit.<br>This bit indicates whether an interrupt (Interrupt Status CHx_END of the DMAC Interrupt Status Register (offset: 80Ch)) is or is not conveyed when processing of this descriptor list is completed.<br>1b: The interrupt is conveyed.<br>0b: The interrupt is not conveyed.                  |
| LS          | List Stop bit.<br>This bit indicates whether DMA transfer is or is not to be stopped on completion of processing for this descriptor list entry.<br>1b: Stopped<br>0b: Not stopped<br><br>On completion of the list in which the setting of this bit is 1b, the QUE_EN bit of the DMA control register is cleared. |
| LABEL[15:0] | This field represents the label of the list.<br>There are no special rules for the setting procedures. The value can be set as desired.                                                                                                                                                                            |

Operations by the settings of the EI and LS bits following the completion of the descriptor list are as follows.

Table 35.7-5 Details of the EI/LS Bits

| EI | LS | Description                                                                                                                                                                                          |
|----|----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0b | 0b | No interrupt. DMA transfer is not stopped. If the queue has a next list, execution of the next descriptor follows.                                                                                   |
| 0b | 1b | No interrupt. DMA transfer is stopped (QUE_EN is cleared).                                                                                                                                           |
| 1b | 0b | Interrupt (DMAC Interrupt Status Register (Offset: 80Ch), Interrupt Status CHx_END) is present. DMA transfer is not stopped. If the queue has a next list, execution of the next descriptor follows. |
| 1b | 1b | Interrupt (DMAC Interrupt Status Register (Offset: 80Ch), Interrupt Status CHx_END) is present. DMA transfer is stopped (QUE_EN is cleared).                                                         |

### (3) Descriptor Format

The table below is the format of descriptors.

Table 35.7-6 Descriptor List Format

| Offset | Byte 3 |  |  |  |  |  |  | Byte 2 |  |  |  |  |  |  | Byte 1 |  |  |  |  |  |  | Byte 0 |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

| FUNC[2:0]  | This field specifies the function number of the request to be issued through the PCIe interface.                                                                                                                                                                                                                                                                                                                                                                               |
| DIR        | <p>This bit indicates the direction of data transfer.</p> <p>1b: AXI → PCIe<br/>           0b: PCIe → AXI</p>                                                                                                                                                                                                                                                                                                                                                                  |
| LP[31:0]   | <p>This field indicates the address where a next descriptor is stored.</p> <p>Since the setting is for 8-byte alignment, do not set a value other than the 3 lower-order bits ([2:0]).</p>                                                                                                                                                                                                                                                                                     |

The conditions where the descriptor is written back after the descriptor is read, the timings, and the corresponding bits are listed below.

| Condition                   | Timing                                                       | Corresponding Bit and Value |
|-----------------------------|--------------------------------------------------------------|-----------------------------|
| WBD = 0b && LV = 1b         | After DMA transfer specified by the descriptor is completed  | LV = 0b                     |
| WBD = (1b or 0b) && LV = 0b | After the descriptor is read (DMA transfer does not proceed) | D = 1b                      |
| WBD = 1b && LV = 1b         | Write-back does not proceed.                                 | —                           |

#### (4) Flow of Operations

The following describes the procedures for settings to activate and stop the DMAC in the case of descriptor-type transfer.

##### (a) Activation and Normal Operation

Before activating the DMAC, set the PCIe and AXI windows. After that, set the registers of the DMAC to start the DMAC.

**(b) Stopping DMA Transfer**

The following describes the procedure for settings to stop DMA transfer under software control.

DMA transfer can be stopped by writing 0b to the QUE\_EN (queue enable) bit (bit [1]) of the DMAC channel control register (offset: 900h + channel offset). Following the detection of QUE\_EN being 0b, the unit waits for the completion of any request which has already been issued before asserting the interrupt signal (DMA\_INT). After waiting for the assertion of DMA\_INT, poll the CHx\_STOP bit of the DMA interrupt status register (offset: 80Ch) to check that its value is 1b. This indicates that DMA transfer has been stopped. If the CHx\_STOP bit is 0b, check the CHx\_END bit for the given channel in the same register. If a last request is still being executed when QUE\_EN is set to 0b, the CHx\_END bit indicates the completion of DMA transfer as in normal operation.

The address to which transfer was most recently completed before it was stopped and the remaining number of bytes for transfer can be checked by reading the DMA status registers (offset: 950h + channel offset to 95Ch + channel offset) for the given channel.

### (c) Error Processing

If an error is detected in the AXI bus or a PCIe link while DMA transfer is in progress, the DMA\_INT interrupt signal is asserted. Check the channel where the error was found (CHx\_ERR = 1b) by using the DMAC interrupt status register and also the type of error by using the DMAC error status register (offset: 968h + channel offset) as required.

Clear the CHx\_ERR bit that is currently set in the DMAC interrupt status register (offset: 80Ch) to 0b by writing to it. The address to which transfer was most recently completed before it was stopped and the remaining number of bytes for transfer can be checked by reading the DMA status registers (offset: 950h + channel offset to 95Ch + channel offset) for the given channel.

Based on that information, setting the registers as described in **Section 35.7.4.2(4)(a), Activation and Normal Operation** and create a descriptor table again. At this time, write 1b to the QUE\_CLR bit (bit [8]) of the DMAC channel control register (offset: 900h + channel offset). Writing 1b to it leads to clearing of the queue. The descriptor lists registered in the queue (those waiting for execution and the one currently being executed) are all cleared.

### 35.7.4.3 Method of Transfer

This section describes the issuing of requests to the AXI or PCIe and data transfer in the case of DMA transfer. In either direction of transfer (from AXI to PCIe or vice versa), a request is issued to the reading side. After confirming the completion of preparation (reception) of the data to be read, a request is issued to the writing side for data transfer.

#### (1) DMA Transfer from PCIe to AXI

An MRd is issued to the PCIe module and an AXI write request is transferred following the reception of CplD from the PCIe. MRd requests corresponding to the number of outstanding transfers can be issued regardless of the reception of CplD. The received CplD (read data) is stored in the data buffer (RAM) once and then transferred by the DMAC to the AXI.

#### (2) DMA Transfer from AXI to PCIe

After the DMAC is activated, a read request (address channel) is issued to the AXI. The reception of data for reading from the given AXI slave starts and an MWr is issued to the PCIe. Data are repeatedly transferred until the completion of DMA data transfer corresponding to the amount of data set in the DMA Size bits.

### 35.7.4.4 Inter-Channel Arbitration

The DMAC arbitrates the following three types of request between channels.

- 1) PCIe Read Request
- 2) AXI Read Request
- 3) AXI Write Request

PCIe write requests do not require arbitration because data read over the AXI are returned one by one.

In the case of arbitration on the AXI side, not only requests for DMA data, but also reading and writing of descriptor data are subject to arbitration (each channel has a single source of requests for arbitration since a channel will not output a descriptor and request for data at the same time).

#### (1) Method of Arbitration

An MRd is issued to the PCIe module and an AXI write request is transferred following the reception of CplD from the PCIe. MRd requests corresponding to the number of outstanding transfers (eight) can be issued regardless of the reception of CplD. The received CplD (read data) is stored in the data buffer (RAM) once and then transferred by the DMAC to the AXI.

Arbitration for each type of request 1) to 3) above proceeds in round-robin fashion. A channel for which execution has just been completed is given the lowest priority and each channel which had a lower priority than that channel is raised by one rank in the order of priority.

The initial order of priority is ch. 0 > ch. 1 > ch. 2 > ch. 3 > ch. 4 > ch. 5 > ch. 6 > ch. 7.

The order of priority is changed every time a single request is completed.

There are two types of request for the AXI, requests for DMA data and requests for descriptors, but they are not distinguished for purposes of arbitration.

#### 35.7.4.5 DMA Completed Interrupt

The DMAC has interrupt functions. It supports two types of interrupt source: one set is for normal operation and the other is for errors. For details, see **Section 35.7.6.5, DMA Interrupt**.

### 35.7.5 Reception of PCIe Commands

#### 35.7.5.1 Reception of MSIs (Root Complex)

Reception of a memory write request in the MSI (message-signaled interrupt) reception area is judged to be an MSI. At this time, the request is forwarded to the AXI as a write transaction and the MSI Receive Interrupt Status bit (bit [4]) of the PCI INTx Receive Interrupt Status Register (offset: 114h) is automatically set at the same time. If the MSI Receive Interrupt Enable bit (bit [4]) of the PCI INTx Receive Interrupt Enable Register (offset: 110h) has been set, the interrupt signal (INTMSI\_RC) is asserted. If the request is identified as an MSI due to the interrupt source, software can pinpoint the source by reading data in memory.

#### The conditions for judging a request to be an MSI

When all of the following conditions are satisfied, a request is judged to be an MSI.

- (1) The request is a memory write request.
- (2) The request is entered for any area within an AXI window.
- (3) The address of an MWr from the PCIe interface must be within the area set by the MSI Reception Window Address register and the MSI Reception Window Mask register.  
If a memory read request is received in the MSI reception area, the request is not judged to be an MSI so an interrupt is not generated.
- (4) The length of memory write requests is 1 dword.

#### Notes on the MSI

- (1) When a response to the MSI write transaction is returned, this unit judges execution of the MSI to have been completed and asserts an interrupt signal. Depending on the system, however, the MSI memory write transaction may not be completed due to the latency over the AXI to the actual memory even if the interrupt signal is asserted. To avoid this problem, buffering of AXI write transactions must be disabled (MAWCACHE[0] = 0b) at the time an MSI is issued.  
For MAWCACHE[3:1], the setting of AWCACHE\_L (bits [27:24]) of Mode Set 0 Register is used.
- (2) If an MSI is received, the MSI write transaction is executed when MAWID[3:0] = 0001b. This is required for the unit to recognize the reception of the response to the MSI and for assertion of INTMSI\_RC.

35.7.5.2 Setting the MSI Window

To enable MSI interrupts, the MSI window must be set. **Figure 35.7-2** shows example settings. The MSI window can be allocated within any AXI window.

Figure 35.7-2 Settings for the MSI Window

### 35.7.5.3 Reception of an Interrupt in Response to a Message Request (Root Complex)

When Assert\_INTx is received in response to an Msg request from the PCIe interface, the corresponding interrupt bit (bits [3] to [0]) is set in the PCI INTx Receive Interrupt Status Register (offset: 114h) and an interrupt (INTx\_RC) is asserted. When Deassert\_INTx is received in response to a message request, the corresponding interrupt register (bit) is cleared and INTx\_RC is de-asserted. The PCI INTx Receive Interrupt Status Register (offset: 114h) can be cleared by writing to it (RW1C) by software. In the PCIe, however, we do not recommend using software to clear an interrupt bit which has been set in response to an Msg in normal operation.

### 35.7.5.4 Reception of Message Requests

When a message is received through the PCIe interface, the relevant information is stored in the following registers.

Table 35.7-7 Message Related Registers

| Related Register     |                                              |
|----------------------|----------------------------------------------|
| Message Code/Routing | Message Code Register (Offset: 130h)         |
| Message Data         | Message Data Register (Offset: 134h)         |
| Message 3rd Header   | Message Header 3rdDW Register (Offset: 138h) |
| Message 4th Header   | Message Header 4thDW Register (Offset: 13Ch) |

The corresponding bit in the Message Receive Interrupt Status Register is set at the same time as the reception of the following messages, and this is indicated by an interrupt.

| Received Message    |              | Corresponding Bit in Message Receive Interrupt Status Register |
|---------------------|--------------|----------------------------------------------------------------|
| Type of Message     | Message Code |                                                                |
| PM_Active_State_Nak | 0001_0100    | Bit [19]                                                       |
| PM_PME              | 0001_1000    | Bit [18]                                                       |
| PME_Turn_Off        | 0001_1001    | Bit [17]                                                       |
| PME_TO_Ack          | 0001_1011    | Bit [16]                                                       |

In the reception of PM messages other than the above, the relevant information is not written to the registers listed in **Table 35.7-7**.

- Unsupported messages:
  - Unlock
  - Vendor Defined Type 0
  - Vendor Defined Type 1

### 35.7.6 Interrupt

This unit prepares the output of interrupt signals in the ways stated below. The states of all interrupt signals are indicated at a glance in the Interrupt Table Register.

#### 35.7.6.1 Error and Event Interrupt Notification

Table 35.7-8 Error/Event Interrupt Outputs

| Interrupt Source Name | Active | Attribute | Description           |
|-----------------------|--------|-----------|-----------------------|
| DMA_INT               | High   | Level     | DMA-related event     |
| PCIE_EVT_INT          | High   | Level     | PCIe-related event    |
| MSG_INT               | High   | Level     | Reception of messages |
| AXI_ERR_INT           | High   | Level     | AXI-related error     |

#### Interrupt Output Related Status Registers

|               |                                                                                                                                                                         |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DMA_INT:      | DMAC Interrupt Status Register (Offset: 80Ch)<br>DMAC Error Status Register (Offset: 968h / + Channel Offset)                                                           |

| MSG_INT:      | Message Receive Interrupt Status Register (Offset: 124h)                                                                                                                |
| AXI_ERR_INT:  | AXI Master Error Interrupt Status Register (Offset: 214h)<br>AXI Slave Error Interrupt Status 1 Register (Offset: 224h)                                                 |

#### (1) Unit-Internal RAM Parity Error Interrupt Notification

The detection of parity errors in the internal RAM of this unit is indicated by the output of interrupt signals in the ways described below. The type of parity error detecting RAM can be confirmed from the corresponding register bit. A breakdown of the device is a possibility.

|               |                                                                                                                |
|---------------|----------------------------------------------------------------------------------------------------------------|
| PCIE_EVT_INT: | PCIe Event Interrupt Status 0 Register (Offset: 204h)<br>PCIe Event Interrupt Status 1 Register (Offset: 20Ch) |
| DMA_INT:      | DMAC Interrupt Status Register (Offset: 80Ch)<br>DMAC Error Status Register (Offset: 968h / + Channel Offset)  |

#### CAUTION

A RAM parity function is not available because it is not implemented in this core.

### 35.7.6.2 INTx/MSI Interrupt Notification (Root Complex)

Table 35.7-9 INTx/MSI Interrupt Outputs

| Interrupt Source Name                                 | Active | Attribute | Description                                                                                                                     |
|-------------------------------------------------------|--------|-----------|---------------------------------------------------------------------------------------------------------------------------------|
| INTA_RC                                               | High   | Level     | Set in response to the reception of an assert INTA message and cleared in response to the reception of a deassert INTA message. |
| INTB_RC                                               | High   | Level     | Set in response to the reception of an assert INTB message and cleared in response to the reception of a deassert INTB message. |
| INTC_RC                                               | High   | Level     | Set in response to the reception of an assert INTC message and cleared in response to the reception of a deassert INTC message. |
| INTD_RC                                               | High   | Level     | Set in response to the reception of an assert INTD message and cleared in response to the reception of a deassert INTD message. |
| INTMSI_RC                                             | High   | Level     | Set when a memory write request comes from the PCIe to the area set in the MSI reception window.                                |
| INT_LINK_BANDWIDTH                                    | High   | Level     | Set when the link width has been changed.                                                                                       |
| INT_PM_PME                                            | High   | Level     | Set in response to the reception of PME event notification (PM_PME message).                                                    |
| INT_SERR_COR/<br>INT_SERR_NONFATAL/<br>INT_SERR_FATAL | High   | Level     | Set in response to the reception of a correctable error message, non-fatal error message, or fatal error message.               |

### 35.7.6.3 Issuing INTx/MSI Interrupts (Endpoint)

An endpoint indicates two types of interrupt to the root complex.

- (1) Legacy interrupt (Assert INTx Message/Deassert INTx Message)
  - Issuing INTx Msg specified by an interrupt register by controlling an interrupt input signal (INTX\_EP\_F\*) (recommended)
  - Issuing Assert INTx and Deassert INTx messages through the issuing of special requests.
- (2) MSI
  - Issuing an MSI by generating a memory write transaction directly.

The MSI Enable bit in the MSI Capability Register (PCIe configuration Register) can be used to switch exclusive operation of two interrupts on or off.

To issue a legacy interrupt, the Interrupt Disable bit in the Command and Status Register (PCIe Configuration Register) must be cleared.

Furthermore, if writing proceeds in a power state other than D0 or a PME\_TURN\_OFF message is received, or if FLR\_REQ is received, Deassert INTx Msg is automatically generated in response to the corresponding function asserting an INTx, and all active interrupts are withdrawn without waiting for the PME\_Turn\_Off Message reception/Non-D0 State transition request reception acknowledge/FLR\_RESET response. However, when multiple functions share an INTx, the logical OR of the signals from the sharing functions is taken, a Deassert INTx Msg is generated, and the interrupts are withdrawn. If INTX\_EP\_F0/F1 is being asserted at the time of returning to the D0 state once more or an FLR sequence is completed (indicated by the de-assertion of FLR\_REQ), Assert INTx is generated again in response.

Table 35.7-10 INTx/MSI Interrupt Inputs

| Interrupt Factor Name | Active | Attribute | Description                                                     |
|-----------------------|--------|-----------|-----------------------------------------------------------------|
| INTX_EP_F0            | High   | Level     | This is the trigger for Assert INTx and Deassert INTx messages. |
| INTX_EP_F1            | High   | Level     |                                                                 |

#### [Related registers]

PCI INTx Out Status Register (Offset: 118h)

### (1) Issuing a Legacy PCI INTx Emulation Interrupt (when MSI Enable = 0b)

A legacy PCI INTx emulation interrupt is issued by controlling INTX\_EP\_F\*.

The type of Assert INTx and Deassert INTx Msg to be issued by controlling an interrupt signal is specified by an interrupt register provided for each of the functions. Assert INTx Msg is issued by setting INTX\_EP\_F\* to 1, and Deassert INTx Msg is issued by clearing INTX\_EP\_F\* to 0.

Make sure that a interrupt signal successfully arrives on the receiving side following the de-assertion of an interrupt signal. After completion of processing for an interrupt from a given source, negating the signal is recommended.

Changing the allocation of the legacy interrupt lines is possible by changing the interrupt register setting of the configuration register. If the same interrupt is shared by multiple functions, the logical OR of INTX\_EP\_F0 and INTX\_EP\_F1 is taken to issue an interrupt.

### (2) MSI Transmission by Interrupt Input (when MSI Enable = 1b)

Five inputs are used in specifying the interrupt (MSI). In the same way, each interrupt indication has its corresponding specified interrupt vector.

Table 35.7-11 External Interrupt Notification

| Interrupt Notification Name   | I/O | Note                                    |
|-------------------------------|-----|-----------------------------------------|
| UI_EXTMSI_VAL0/1/2/3/4        | I   | Interrupt notification                  |
| UI_EXTMSI_VEC0/1/2/3/4 [4:0]  | I   | Interrupt vector specification          |
| UI_EXTMSI_FUNC0/1/2/3/4 [4:0] | I   | Interrupt function number specification |

**Note:** Multiple Message Enable in the Base Spec.: Implemented as a specification that supports 32 (5 bits).  
Multiple Message Enable on the RC side: Support for 32 is also required.

#### CAUTION

Take care that the specified vector value does not impose a related restriction on the Multiple Message Enable register. For example, if the number set for Multiple Message Enable is 4, the two lower-order bits within the value set for the Message Data are overwritten by the value specified for the UI\_EXTMSI\_VEC[\*] bits, and at that time, specify the value 0 for the higher-order bits that are not overwritten by UI\_EXTMSI\_VEC[\*] bits. Convey interrupts in the state where the vector value and function number have been specified.

### (3) Flow of Asserting MSI Enable

The following is the flow of asserting the MSI Enable field (bit 16) of the MSI Capability register.

1. Negate all INTx\_EP\_F0/F1 (processing by the endpoint).
2. Wait until the Interrupt Status field (bit 19) of the Command and Status register becomes 0b (confirm that the device is not in the waiting state for INTx interrupt messages).  
(Processing by the root complex: CfgRd)
3. Write 1b to the MSI Enable field (bit 16) of the MSI Capability register.  
(Processing by the root complex: CfgWr)

### 35.7.6.4 Root Complex Interrupt Notification

When this unit is in the root complex configuration, it has the following interrupt sources.

- INT\_LINK\_BAND\_WIDTH
- INT\_PM\_PME
- INT\_SERR
- INT\_SERR\_COR
- INT\_SERR\_FATAL
- INT\_SERR\_NONFATAL

#### (1) Interrupt due to the Change to the Link Bandwidth (INT\_LINK\_BAND\_WIDTH)

This interrupt source is conveyed in response to the change to the bandwidth in link negotiation of PCI Express.

Note that this interrupt source is enabled when the root complex is in use and it is fixed to “0: Low” when the endpoint is in use.

This interrupt source is only enabled when the Link Bandwidth Notification Capability bit (bit 21) of the Link Capabilities register (offset: 60Ch) is set to 1b. This interrupt signal can also be disabled by setting the Link Bandwidth Notification Capability bit to 0b even in operation as the root complex.

If the Link Bandwidth Notification Capability bit (bit 21) is set to 1b, the Link Bandwidth Management Status bit (bit 30) and the Link Autonomous Bandwidth Status bit (bit 31) in the Link Status register (offset 70h) serve as a source of the interrupt. These bits are set to 1b when the bandwidth is changed.

Whether to enable this interrupt source corresponds to the respective states of the Link Bandwidth Management Interrupt Enable bit (bit 10) and the Link Autonomous Bandwidth Interrupt Enable (bit 11) of the Link Control register (offset: 70h).

#### [Related Registers]

| Offset                                                  | Bit | Description                                |
|---------------------------------------------------------|-----|--------------------------------------------|
| PCI Express Capability Structure: Link Control / Status |     |                                            |
| 06Ch                                                    | 21  | Link Bandwidth Notification Capability     |
| 070h                                                    | 10  | Link Bandwidth Management Interrupt Enable |
|                                                         | 11  | Link Autonomous Bandwidth Interrupt Enable |
|                                                         | 30  | Link Bandwidth Management Status           |
|                                                         | 31  | Link Autonomous Bandwidth Status           |

**(2) PM-PME Reception Interrupt (INT\_PM\_PME)**

This interrupt source is conveyed when the notification of a PME event (PM\_PME message) is received from the other-party device.

Note that this interrupt source is enabled when the root complex is in use and it is fixed to “0: Low” when the endpoint is in use.

This interrupt source is only conveyed when the PME Interrupt Enable bit (bit 3) of the Root Control/Capabilities Register (offset: 7Ch) is set to 1b. This interrupt source is not conveyed when the PME Interrupt Enable bit (bit 3) is set to 0b.

Note that the reception state of the received PM\_PME message and the ID information, etc. are stored in the Root Status Register (offset: 80h) regardless of the setting of the PME Interrupt Enable bit mentioned above.

**[Related Registers]**

| Offset                                                      | Bit  | Description          |
|-------------------------------------------------------------|------|----------------------|
| PCI Express Capability Structure: Root Control Capabilities |      |                      |
| 07Ch                                                        | 3    | PME Interrupt Enable |
| PCI Express Capability Structure: Root Status               |      |                      |
| 080h                                                        | 15:0 | PME Requester ID     |
|                                                             | 16   | PME Status           |
|                                                             | 17   | PME Pending          |

**(3) System Error Interrupt (INT\_SERR\_xxx)**

This interrupt is conveyed when a correctable error message, non-fatal error message, or fatal error message is received.

INT\_SERR: The system error notification mentioned in the Base Spec. is obtained as the logical OR of the following three signals.

INT\_SERR\_COR: System Error on Correctable Error

INT\_SERR\_FATAL: System Error on Fatal Error

INT\_SERR\_NONFATAL: System Error on Non-Fatal Error

These interrupt sources are enabled when the root complex is in use and these are fixed to “0: Low” when the endpoint is in use.

**(a) Correctable Error Interrupt (INT\_SERR\_COR)**

To proceed with interrupt control due to a correctable error, set the interrupt enable bits of the following registers to 1b.

| No. | Offset                                                        | Bit | Description                        |
|-----|---------------------------------------------------------------|-----|------------------------------------|
| 1   | PCI Compatible Configuration: Bridge Control and Interrupt    |     |                                    |
|     | 03Ch                                                          | 17  | SERR# Enable                       |
| 2   | PCI Express Capability Structure: Device Control              |     |                                    |
|     | 068h                                                          | 0   | Correctable Error Reporting Enable |
| 3   | Advanced Error Reporting (AER) Capability: Root Error Command |     |                                    |
|     | 12Ch                                                          | 0   | Correctable Error Reporting Enable |

<Interrupt Source>

**(1) ERR\_COR Message Reception**

If an ERR\_COR message is received from the other-party device (endpoint), the INT\_SERR\_COR interrupt will be asserted. The following status register will be set at the same time.

| Offset                                                       | Bit | Description      |
|--------------------------------------------------------------|-----|------------------|
| Advanced Error Reporting (AER) Capability: Root Error Status |     |                  |
| 130h                                                         | 0   | ERR_COR Received |

**Note:** If the Enable bits in no. 1, 2, and 3 are not set, the interrupt source will not be generated.  
If the Enable bits in no. 1 and 2 are not set, writing will be masked.

## (2) Correctable Error Detection

Any of the following correctable errors being detected within the unit will be written to the corresponding status register.

| Error                                                               | Offset | Bit | Description                     |
|---------------------------------------------------------------------|--------|-----|---------------------------------|
| Advanced Error Reporting (AER) Capability: Correctable Error Status |        |     |                                 |
| 8B10B Decode Error<br>8B10B RD Error                                | 110h   | 0   | Receiver Error Status           |
| Bad TLP                                                             |        | 6   | Bad TLP Status                  |
| Bad DLLP                                                            |        | 7   | Bad DLLP Status                 |
| REPLAY_NUM Roll over                                                |        | 8   | REPLAY_NUM Rollover Status      |
| Replay Timer Timeout                                                |        | 12  | Replay Timer Timeout Status     |
| Advisory Non-Fatal Error                                            |        | 13  | Advisory Non-Fatal Error Status |

**Note:** If the Mask bit (Correctable Error Mask Register: Offset 114h) corresponding to each bit is set (masked), the corresponding error will not be detected and the interrupt source will not be generated.

At the same time, the INT\_SERR\_COR interrupt will be generated and the following status registers will be set to 1b.

| Offset                                                        | Bit | Description              |
|---------------------------------------------------------------|-----|--------------------------|
| PCI Express Capability Structure: Device Status               |     |                          |
| 068h                                                          | 16  | Correctable Error Detect |
| Advanced Error Reporting (AER) Capability : Root Error Status |     |                          |
| 130h                                                          | 0   | ERR_COR Received         |

**Note:** If the Enable bit in no. 2 is not set, the interrupt source will not be generated.  
If the Enable bit in no. 2 is not set, writing to the Root Error Status Register will be masked.

If the Correctable Error Reporting Enable bit listed in no. 3 is not set, the source due to (1) and (2) stated above will be generated and INT\_SERR\_COR will not be asserted even if writing to the Root Error Register has proceeded.

**(b) Fatal Error Interrupt (INT\_SERR\_FATAL)**

To proceed with interrupt control due to a fatal error, set the interrupt enable bits of the following registers to 1b.

| No. | Offset                                                        | Bit | Description                  |
|-----|---------------------------------------------------------------|-----|------------------------------|
| 1   | PCI Compatible Configuration: Bridge Control and Interrupt    |     |                              |
|     | 03Ch                                                          | 17  | SERR# Enable                 |
| 2   | PCI Express Capability Structure: Device Control              |     |                              |
|     | 068h                                                          | 2   | Fatal Error Reporting Enable |
| 3   | Common Configuration Space: Command and Status                |     |                              |
|     | 004h                                                          | 8   | SERR# Enable                 |
| 4   | Advanced Error Reporting (AER) Capability: Root Error Command |     |                              |
|     | 12Ch                                                          | 2   | Fatal Error Reporting Enable |

## &lt;Interrupt Source&gt;

**(1) ERR\_FATAL Message Reception**

If an ERR\_FATAL message is received from the other-party device (endpoint), the INT\_SERR\_FATAL interrupt will be asserted (if the Enable bits in no.1 and 2 or no.3 and 4 are not set, the interrupt source will not be generated). The following status registers will be set at the same time.

| Offset                                                       | Bit | Description                  | Remarks |
|--------------------------------------------------------------|-----|------------------------------|---------|
| Type1 Configuration Space: Secondary Status                  |     |                              | *1      |
| 01Ch                                                         | 30  | Received System Error        |         |
| Common Configuration Space: Status Register                  |     |                              | *2      |
| 004h                                                         | 30  | Signaled System Error        |         |
| Advanced Error Reporting (AER) Capability: Root Error Status |     |                              | *3      |
| 130h                                                         | 6   | Fatal Error Message Received |         |

Note 1. Writing to this status register proceeds at the point a message is received regardless of the settings of the Enable bits.

Note 2. If the Enable bits in no. 1 and 2 are not set, writing will be masked.

Note 3. If the Enable bit in no. 1, 2, or 3 is not set, writing will be masked.

**(2) Fatal Error Detection**

Any of the following fatal errors being detected within the unit will be written to the corresponding status register.

| Error                                                                 | Offset | Bit | Description                      |
|-----------------------------------------------------------------------|--------|-----|----------------------------------|
| Advanced Error Reporting (AER) Capability: Uncorrectable Error Status |        |     |                                  |
| Data Link Protocol Error                                              | 104h   | 4   | Data Link Protocol Error Status  |
| Poisoned TLP                                                          |        | 12  | Poisoned TLP Status              |
| Completion Timeout                                                    |        | 14  | Completion Timeout Status        |
| Completer Abort                                                       |        | 15  | Completer Abort Status           |
| Unexpected Completion                                                 |        | 16  | Unexpected Completion Status     |
| Receiver Overflow                                                     |        | 17  | Receiver Overflow Status         |
| Malformed TLP                                                         |        | 18  | Malformed TLP Status             |
| ECRC Error                                                            |        | 19  | ECRC Error Status                |
| Unsupported Request                                                   |        | 20  | Unsupported Request Error Status |

**Note:** If the Mask bit (Uncorrectable Error Mask Register: Offset 108h) corresponding to each bit is set (masked), the corresponding error will not be detected and the interrupt source will not be generated.

Also, the setting of the corresponding Severity bit (Uncorrectable Error Severity: Offset 10Ch) must be 1b (Fatal).

The INT\_SERR\_FATAL interrupt will be generated at the same time (if the Enable bits in no. 2 or no.3 and 4 are not set, the interrupt source will not be generated). The following status registers will be set at the same time.

| Offset                                                       | Bit | Description                  | Remarks |
|--------------------------------------------------------------|-----|------------------------------|---------|
| PCI Express Capability Structure: Device Status              |     |                              |         |
| 068h                                                         | 18  | Fatal Error Detect           |         |
| Common Configuration Space: Status Register                  |     |                              | *1      |
| 004h                                                         | 30  | Signaled System Error        | *2      |
| Advanced Error Reporting (AER) Capability: Root Error Status |     |                              |         |
| 130h                                                         | 6   | Fatal Error Message Received |         |

Note 1. If the Enable bit in no. 3 is not set, writing will be masked.

Note 2. If the Enable bit in no. 2 or 3 is not set, writing will be masked.

If the Fatal Error Reporting Enable bit listed in no. 4 is not set, the source due to (1) and (2) stated above will be generated and INT\_SERR\_FATAL will not be generated even if writing to the Root Error Status Register has proceeded.

**(c) Non-Fatal Error Interrupt (INT\_SERR\_NONFATAL)**

To proceed with interrupt control due to a non-fatal error, set the interrupt enable bits of the following registers to 1b.

| No. | Offset                                                        | Bit | Description                      |
|-----|---------------------------------------------------------------|-----|----------------------------------|
| 1   | PCI Compatible Configuration: Bridge Control and Interrupt    |     |                                  |
|     | 03Ch                                                          | 17  | SERR# Enable                     |
| 2   | PCI Express Capability Structure: Device Control              |     |                                  |
|     | 068h                                                          | 1   | Non-Fatal Error Reporting Enable |
| 3   | Common Configuration Space: Command and Status                |     |                                  |
|     | 004h                                                          | 8   | SERR# Enable                     |
| 4   | Advanced Error Reporting (AER) Capability: Root Error Command |     |                                  |
|     | 12Ch                                                          | 1   | Non-Fatal Error Reporting Enable |

## &lt;Interrupt Source&gt;

**(1) ERR\_FATAL Message Reception**

If an ERR\_NONFATAL message is received from the other-party device (endpoint), the INT\_SERR\_NONFATAL interrupt will be generated (if the Enable bits in no.1 and 2 or no.3 and 4 are not set, the interrupt source will not be generated). The following status registers will be set at the same time.

| Offset                                                       | Bit | Description                      | Remarks |
|--------------------------------------------------------------|-----|----------------------------------|---------|
| Type1 Configuration Space: Secondary Status                  |     |                                  | *1      |
| 01Ch                                                         | 30  | Received System Error            |         |
| Common Configuration Space: Status Register                  |     |                                  | *2      |
| 004h                                                         | 30  | Signaled System Error            |         |
| Advanced Error Reporting (AER) Capability: Root Error Status |     |                                  | *3      |
| 130h                                                         | 5   | Non-Fatal Error Message Received |         |

Note 1. Writing to this status register proceeds at the point a message is received regardless of the settings of the Enable bits.

Note 2. If the Enable bits in no. 1 and 3 are not set, writing will be masked.

Note 3. If the Enable bit in no. 1, 2, or 3 is not set, writing will be masked.

**(2) Non-Fatal Error Detection**

Any of the following non-fatal errors being detected within the unit will be written to the corresponding status register.

| Error                                                                 | Offset | Bit | Description                      |
|-----------------------------------------------------------------------|--------|-----|----------------------------------|
| Advanced Error Reporting (AER) Capability: Uncorrectable Error Status |        |     |                                  |
| Data Link Protocol Error                                              | 104h   | 4   | Data Link Protocol Error Status  |
| Poisoned TLP                                                          |        | 12  | Poisoned TLP Status              |
| Completion Timeout                                                    |        | 14  | Completion Timeout Status        |
| Completer Abort                                                       |        | 15  | Completer Abort Status           |
| Unexpected Completion                                                 |        | 16  | Unexpected Completion Status     |
| Receiver Overflow                                                     |        | 17  | Receiver Overflow Status         |
| Malformed TLP                                                         |        | 18  | Malformed TLP Status             |
| ECRC Error                                                            |        | 19  | ECRC Error Status                |
| Unsupported Request                                                   |        | 20  | Unsupported Request Error Status |

**Note:** If the Mask bit (Uncorrectable Error Mask Register: Offset 108h) corresponding to each bit is set (masked), the corresponding error will not be detected and the interrupt source will not be generated.

Also, the setting of the corresponding Severity bit (Uncorrectable Error Severity: Offset 10Ch) must be 0b (Non-fatal).

The INT\_SERR\_NONFATAL interrupt will be generated at the same time (if the Enable bits in no. 2 or no.3 and 4 are not set, the interrupt source will not be generated). The following status registers will be set at the same time.

| Offset                                                       | Bit | Description                      | Remarks |
|--------------------------------------------------------------|-----|----------------------------------|---------|
| PCI Express Capability Structure: Device Status              |     |                                  | *1      |
| 068h                                                         | 17  | Non-Fatal Error Detect           |         |
| Common Configuration Space : Status Register                 |     |                                  | *1      |
| 004h                                                         | 30  | Signaled System Error            |         |
| Advanced Error Reporting (AER) Capability: Root Error Status |     |                                  | *2      |
| 130h                                                         | 5   | Non-Fatal Error Message Received |         |

Note 1. If the Enable bit in no. 3 is not set, writing will be masked.

Note 2. If the Enable bit in no. 2 or 3 is not set, writing will be masked.
